 $-92 = 1010\ 0100$  No overflow – carry into leftmost position and carry out
5.  $+57 = 0011\ 1001$   
 $+92 = 0101\ 1100$   

---

 $+149 = *1001\ 0101$  \*Overflow – carry into leftmost position, no carry out
6.  $-57 = 1100\ 0111$   
 $-92 = 1010\ 0100$   

---

 $-149 = *0110\ 1011$  \*Overflow – no carry into leftmost position but carry out

The presence or absence of an overflow condition may be recognized from the carries:

- There is no overflow:
  1. If there is no carry into the leftmost bit position and no carry out (examples 1 and 3).
  2. If there is a carry into the leftmost position and also a carry out (examples 2 and 4).
- There is an overflow:
  1. If there is a carry into the leftmost position but no carry out (example 5).
  2. If there is no carry into the leftmost position but there is a carry out (example 6).

The following are 16-bit signed binary integers. The first is the maximum positive 16-bit binary integer. The last is the maximum negative 16-bit binary integer (the negative 16-bit binary integer with the greatest absolute value).

$$\begin{aligned}
 2^{15}-1 &= 32,767 = 0\ 111\ 1111\ 1111\ 1111 \\
 2^0 &= 1 = 0\ 000\ 0000\ 0000\ 0001 \\
 0 &= 0 = 0\ 000\ 0000\ 0000\ 0000 \\
 -2^0 &= -1 = 1\ 111\ 1111\ 1111\ 1111 \\
 -2^{15} &= -32,768 = 1\ 000\ 0000\ 0000\ 0000
 \end{aligned}$$

Figure A-1 illustrates several 32-bit signed binary integers arranged in descending order. The first is the maximum positive binary integer that can be represented by 32 bits, and the last is the maximum negative binary integer that can be represented by 32 bits.

|             |                  |                                       |

Figure A-1. 32-Bit Signed Binary Integers

## Unsigned Binary Integers

Certain instructions, such as ADD LOGICAL, treat

binary integers as unsigned rather than signed. Unsigned binary integers have the same format as

signed binary integers, except that the leftmost bit is interpreted as another numeric bit rather than a sign bit. There is no complement notation because all unsigned binary integers are considered positive.

The following examples illustrate the addition of unsigned binary integers. Only eight bit positions are used. The examples are numbered the same as the corresponding examples for signed binary integers.

$$\begin{array}{r} 1. \quad 57 = 0011 \ 1001 \\ \quad 35 = 0010 \ 0011 \\ \hline \quad 92 = 0101 \ 1100 \end{array}$$

$$\begin{array}{r} 2. \quad 57 = 0011 \ 1001 \\ \quad 221 = 1101 \ 1101 \\ \hline \quad 278 = *0001 \ 0110 \text{ *Carry out of leftmost position} \end{array}$$

$$\begin{array}{r} 3. \quad 35 = 0010 \ 0011 \\ \quad 199 = 1100 \ 0111 \\ \hline \quad 234 = 1110 \ 1010 \end{array}$$

|            |                 |                                           |
|------------|-----------------|-------------------------------------------|
| $2^{32}-1$ | = 4 294 967 295 | = 1111 1111 1111 1111 1111 1111 1111 1111 |
| $2^{31}$   | = 2 147 483 648 | = 1000 0000 0000 0000 0000 0000 0000 0000 |
| $2^{31}-1$ | = 2 147 483 647 | = 0111 1111 1111 1111 1111 1111 1111 1111 |
| $2^{16}$   | = 65 536        | = 0000 0000 0000 0001 0000 0000 0000 0000 |
| $2^0$      | = 1             | = 0000 0000 0000 0000 0000 0000 0000 0001 |
| 0          | = 0             | = 0000 0000 0000 0000 0000 0000 0000 0000 |

Figure A-2. 32-Bit Unsigned Binary Integers

## Decimal Integers

Decimal integers consist of one or more decimal digits and a sign. Each digit and the sign are represented by a 4-bit code. The decimal digits are in binary-coded decimal (BCD) form, with the values 0-9 encoded as 0000-1001. The sign is usually represented as 1100 (C hex) for plus and 1101 (D hex) for minus. These are the preferred sign codes, which are generated by the machine for the results of decimal-arithmetic operations. There are also several alternate sign codes (1010, 1110, and 1111 for plus; 1011 for minus). The alternate sign codes are accepted by the machine as valid in source operands but are not generated for results.

Decimal integers may have different lengths, from one to 16 bytes. Of the many decimal formats, only

$$\begin{array}{r} 4. \quad 199 = 1100 \ 0111 \\ \quad 221 = 1101 \ 1101 \\ \hline \quad 420 = *1010 \ 0100 \text{ *Carry out of leftmost position} \end{array}$$

$$\begin{array}{r} 5. \quad 57 = 0011 \ 1001 \\ \quad 92 = 0101 \ 1100 \\ \hline \quad 149 = 1001 \ 0101 \end{array}$$

$$\begin{array}{r} 6. \quad 199 = 1100 \ 0111 \\ \quad 164 = 1010 \ 0100 \\ \hline \quad 363 = *0110 \ 1011 \text{ *Carry out of leftmost position} \end{array}$$

A carry out of the leftmost bit position may or may not imply an overflow, depending on the application.

Figure A-2 illustrates several 32-bit unsigned binary integers arranged in descending order.

two will be considered here: signed-packed-decimal and zoned. In the signed-packed-decimal format, each byte contains two decimal digits, except for the rightmost byte, which contains the sign code in the right half. For decimal arithmetic, the number of decimal digits in the signed-packed-decimal format can vary from one to 31. Because decimal integers must consist of whole bytes and there must be a sign code on the right, the number of decimal digits in this format is always odd. If an even number of significant digits is desired, a leading zero must be inserted on the left.

In the zoned format, each byte consists of a decimal digit on the right and the zone code 1111 (F hex) on the left, except for the rightmost byte where the sign code replaces the zone code. Thus, a decimal integer in the zoned format can have from one to 16 digits. The zoned format may be used directly for input

and output in the extended binary-coded-decimal interchange code (EBCDIC), except that the sign must be separated from the rightmost digit and handled as a separate character. For positive (unsigned) numbers, however, the sign can simply be represented by the zone code of the rightmost digit because the zone code is one of the acceptable alternate codes for plus.

In either format, negative decimal integers are represented in true notation with a separate sign. As for binary integers, the radix point (decimal point) of decimal integers is considered to be fixed at the right, and any scaling is done by the programmer.

The following are some examples of decimal integers shown in hexadecimal notation:

| Decimal Value | Signed Packed Format             | Zoned Format                                 |
|---------------|----------------------------------|----------------------------------------------|
| +123          | 12 3C<br>or<br>12 3F             | F1 F2 C3<br>or<br>F1 F2 F3                   |
| -4321         | 04 32 1D                         | F4 F3 F2 D1                                  |
| +000050       | 00 00 05 0C<br>or<br>00 00 05 0F | F0 F0 F0 F0 F5 C0<br>or<br>F0 F0 F0 F0 F5 F0 |
| -7            | 7D                               | D7                                           |
| 00000         | 00 00 0C<br>or<br>00 00 0F       | F0 F0 F0 F0 C0<br>or<br>F0 F0 F0 F0 F0       |

Under some circumstances, a zero with a minus sign (negative zero) is produced. For example, the multiplicand:

00 12 3D (-123)

times the multiplier:

0C (+0)

generates the product:

00 00 0D (-0)

because the product sign follows the algebraic rule of signs even when the value is zero. A negative zero,

however, is equivalent to a positive zero in that they compare equal in a decimal comparison.

## Hexadecimal-Floating-Point Numbers

A hexadecimal-floating-point (HFP) number is expressed as a hexadecimal fraction multiplied by a separate power of 16. The term floating point indicates that the placement, of the radix (hexadecimal) point, or scaling, is automatically maintained by the machine.

The part of an HFP number which represents the significant digits of the number is called the fraction. A second part specifies the power (exponent) to which 16 is raised and indicates the location of the radix point of the number. The fraction and exponent may be represented by 32 bits (short format), 64 bits (long format), or 128 bits (extended format).

### Short HFP Number

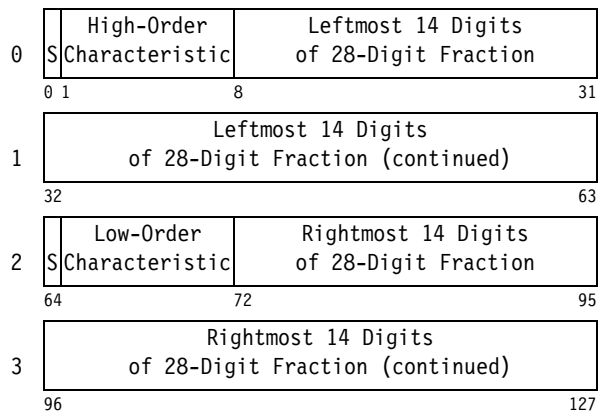

### Long HFP Number

Word

### Extended HFP Number

Word

An HFP number has two signs: one for the fraction and one for the exponent. The fraction sign, which is also the sign of the entire number, is the leftmost bit of each format (0 for plus, 1 for minus). The numeric part of the fraction is in true notation regardless of the sign. The numeric part is contained in bits 8-31 for the short format, in bits 8-63 for the long format, and in bits 8-63 followed by bits 72-127 for the extended format.

The exponent sign is obtained by expressing the exponent in excess-64 notation; that is, the exponent is added as a signed number to 64. The resulting number is called the characteristic. It is located in bits 1-7 for all formats. The characteristic can vary from 0 to 127, permitting the exponent to vary from -64 through 0 to +63. This provides a scale multiplier in the range of  $16^{-64}$  to  $16^{+63}$ . A nonzero fraction, if normalized, has a value less than one and greater than or equal to 1/16, so that the range covered by the magnitude M of a normalized floating-point number is:

$$16^{-65} \leq M < 16^{63}$$

In decimal terms:

$$16^{-65} \text{ is approximately } 5.4 \times 10^{-79}$$

$$16^{63} \text{ is approximately } 7.2 \times 10^{75}$$

|                       |                                          |                                                         |
|-----------------------|------------------------------------------|---------------------------------------------------------|
| 1.0                   | = +1/16x16 <sup>1</sup>                  | = 0 100 0001 0001 0000 0000 0000 0000 0000 <sub>2</sub> |
| 0.5                   | = +8/16x16 <sup>0</sup>                  | = 0 100 0000 1000 0000 0000 0000 0000 0000 <sub>2</sub> |
| 1/64                  | = +4/16x16 <sup>-1</sup>                 | = 0 011 1111 0100 0000 0000 0000 0000 0000 <sub>2</sub> |
| 0.0                   | = +0 x16 <sup>-64</sup>                  | = 0 000 0000 0000 0000 0000 0000 0000 0000 <sub>2</sub> |
| -15.0                 | = -15/16x16 <sup>1</sup>                 | = 1 100 0001 1111 0000 0000 0000 0000 0000 <sub>2</sub> |
| 5.4x10 <sup>-79</sup> | ≈ +1/16x16 <sup>-64</sup>                | = 0 000 0000 0001 0000 0000 0000 0000 0000 <sub>2</sub> |
| 7.2x10 <sup>75</sup>  | ≈ (1-16 <sup>-6</sup> )x16 <sup>63</sup> | = 0 111 1111 1111 1111 1111 1111 1111 1111 <sub>2</sub> |

Figure A-3. Normalized Short Hexadecimal-Floating-Point Numbers

## Conversion Example

Convert the decimal number 59.25 to a short HFP number. (In another appendix are tables for the conversion of hexadecimal and decimal integers and fractions.)

1. The number is separated into a decimal integer and a decimal fraction.

$$59.25 = 59 \text{ plus } 0.25$$

More precisely,

In the short format:

$$16^{-65} \leq M \leq (1 - 16^{-6}) \times 16^{63}$$

In the long format:

$$16^{-65} \leq M \leq (1 - 16^{-14}) \times 16^{63}$$

In the extended format:

$$16^{-65} \leq M \leq (1 - 16^{-28}) \times 16^{63}$$

Within a given fraction length (6, 14, or 28 digits), an HFP operation will provide the greatest precision if the fraction is normalized. A fraction is normalized when the leftmost digit (bit positions 8, 9, 10, and 11) is nonzero. It is unnormalized if the leftmost digit contains all zeros.

If normalization of the operand is desired, the HFP instructions that provide automatic normalization are used. This automatic normalization is accomplished by left-shifting the fraction (four bits per shift) until a nonzero digit occupies the leftmost digit position. The characteristic is reduced by one for each digit shifted.

Figure A-3 illustrates sample normalized short HFP numbers. The last two numbers represent the smallest and the largest positive normalized numbers.

2. The decimal integer is converted to its hexadecimal representation.

$$59_{10} = 3B_{16}$$

3. The decimal fraction is converted to its hexadecimal representation.

$$0.25_{10} = 0.4_{16}$$

4. The integral and fractional parts are combined and expressed as a fraction times a power of 16 (exponent).

$$3B.4_{16} = 0.3B4_{16} \times 16^2$$

- The characteristic is developed from the exponent and converted to binary.

$$\begin{array}{rcl} \text{base} + \text{exponent} & = & \text{characteristic} \\ 64 + 2 & = & 66 = 1000010 \end{array}$$

- The fraction is converted to binary and grouped hexadecimally.

$$.3B4_{16} = .0011\ 1011\ 0100$$

- The characteristic and the fraction are stored in the short format. The sign position contains the sign of the fraction.

| S | Char    | Fraction                      |
|---|---------|-------------------------------|
| 0 | 1000010 | 0011 1011 0100 0000 0000 0000 |

Examples of instruction sequences that may be used to convert between signed binary integers and HFP numbers are shown in “Hexadecimal-Floating-Point-Number Conversion” on page A-44.

---

## Instruction-Use Examples

The following examples illustrate the use of many of the unprivileged instructions. Before studying one of these examples, the reader should consult the instruction description.

The instruction-use examples are written principally for assembler-language programmers, to be used in conjunction with the appropriate assembler-language publications.

Most examples present one particular instruction, both as it is written in an assembler-language statement and as it appears when assembled in storage (machine format).

## Machine Format

All machine-format values are given in hexadecimal notation unless otherwise specified. Storage addresses are also given in hexadecimal. Hexadecimal operands are shown converted into binary, decimal, or both if such conversion helps to clarify the example for the reader.

## Assembler-Language Format

In assembler-language statements, registers and lengths are presented in decimal. Displacements, immediate operands, and masks may be shown in decimal, hexadecimal, or binary notation; for example, 12, X'C', and B'1100' represent the same value. Whenever the value in a register or storage location is referred to as “not significant,” this value is replaced during the execution of the instruction.

When SS-format instructions are written in the assembler language, lengths are given as the total number of bytes in the field. This differs from the machine definition, in which the length field specifies the number of bytes to be added to the field address to obtain the address of the last byte of the field. Thus, the machine length is one less than the assembler-language length. The assembler program automatically subtracts one from the length specified when the instruction is assembled.

In some of the examples, symbolic addresses are used in order to simplify the examples. In assembler-language statements, a symbolic address is represented as a mnemonic term written in all capitals, such as FLAGS, which may denote the address of a storage location containing data or program-control information. When symbolic addresses are used, the assembler supplies actual base and displacement values according to the programmer's specifications. Therefore, the actual values for base and displacement are not shown in the assembler-language format or in the machine-language format. For assembler-language formats, in the labels that designate instruction fields, the letter “S” is used to indicate the combination of base and displacement fields for an operand address. (For example, S2 represents the combination of B2 and D2.) In the machine-language format, the base and displacement address components are shown as asterisks (\*\*\*\*).

## Addressing Mode in Examples

Except where otherwise specified, the examples assume the 24-bit addressing mode.

---

## General Instructions

(See Chapter 7, “General Instructions” for a complete description of the general instructions.)

## ADD HALFWORD (AH)

The ADD HALFWORD instruction algebraically adds the contents of a two-byte field in storage to the contents of a register. The storage operand is expanded to 32 bits after it is fetched and before it is used in the add operation. The expansion consists in propagating the leftmost (sign) bit 16 positions to the left. For example, assume that the contents of storage locations 2000-2001 are to be added to register 5. Initially:

Register 5 contains 00 00 00 19 =  $25_{10}$ .

Storage locations 2000-2001 contain FF FE =  $-2_{10}$ .

Register 12 contains 00 00 18 00.

Register 13 contains 00 00 01 50.

The format of the required instruction is:

### Machine Format

| Op Code | R <sub>1</sub> | X <sub>2</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----------------|----------------|----------------|----------------|
| 4A      | 5              | D              | C              | 6B0            |

### Assembler Format

Op Code R<sub>1</sub>,D<sub>2</sub>(X<sub>2</sub>,B<sub>2</sub>)

AH 5,X'6B0'(13,12)

After the instruction is executed, register 5 contains 00 00 00 17 =  $23_{10}$ . Condition code 2 is set to indicate a result greater than zero.

## AND (N, NC, NI, NR)

When the Boolean operator AND is applied to two bits, the result is one when both bits are one; otherwise, the result is zero. When two bytes are ANDed, each pair of bits is handled separately; there is no connection from one bit position to another. The following is an example of ANDing two bytes:

First-operand byte: 0011 0101<sub>2</sub>

Second-operand byte: 0101 1100<sub>2</sub>

Result byte: 0001 0100<sub>2</sub>

## NI Example

A frequent use of the AND instruction is to set a particular bit to zero. For example, assume that storage location 4891 contains 0100 0011<sub>2</sub>. To set the rightmost bit of this byte to zero without affecting the other bits, the following instruction can be used (assume that register 8 contains 00 00 48 90):

### Machine Format

| Op Code | I <sub>2</sub> | B <sub>1</sub> | D <sub>1</sub> |
|---------|----------------|----------------|----------------|
| 94      | FE             | 8              | 001            |

### Assembler Format

Op Code D<sub>1</sub>(B<sub>1</sub>),I<sub>2</sub>

NI 1(8),X'FE'

When this instruction is executed, the byte in storage is ANDed with the immediate byte (the I<sub>2</sub> field of the instruction):

Location 4891: 0100 0011<sub>2</sub>

Immediate byte: 1111 1110<sub>2</sub>

Result: 0100 0010<sub>2</sub>

The resulting byte, with bit 7 set to zero, is stored back in location 4891. Condition code 1 is set.

## Linkage Instructions (BAL, BALR, BAS, BASR, BASSM, BSM)

Four unprivileged instructions (BRANCH AND LINK, BRANCH AND SAVE, BRANCH AND SAVE AND SET MODE, and BRANCH AND SET MODE) are available, together with the unconditional branch (BRANCH ON CONDITION with a mask of 15), to provide linkage between subroutines. BRANCH AND LINK (BAL or BALR) is provided primarily for compatibility with programs written for System/370; BRANCH AND SAVE (BAS or BASR) is recommended instead for programs which are to be executed using ESA/370. The instructions BRANCH AND SAVE AND SET MODE (BASSM) and BRANCH AND SET MODE (BSM) provide subroutine linkage together with switching between the 24-bit and the 31-bit addressing modes. The use of these instructions is discussed in a programming note at the end of "Subroutine Linkage without the Linkage Stack." (See also the semiprivileged instruction BRANCH AND STACK.)

The following example compares the operation of these instructions and of the unconditional-branch instruction **BRANCH ON CONDITION** (BC or BCR with a mask of 15). Assume that each instruction in turn is located at the current instruction address, ready to be executed next. For the first set of examples, the addressing-mode bit, PSW bit 32, is initially zero (24-bit addressing in effect). For the second set, PSW bit 32 is initially one (31-bit addressing). Assume also that general register 5 is to receive the linkage information, and that general register 6 contains the branch address.

The format of the BALR instruction is:

Machine Format

| Op Code | R <sub>1</sub> | R <sub>2</sub> |
|---------|----------------|----------------|
| 05      | 5              | 6              |

Assembler Format

| Op Code | R <sub>1</sub> , R <sub>2</sub> |
|---------|---------------------------------|
| BALR    | 5,6                             |

The other linkage instructions in the RR format have the same format but different op codes:

BASR 0D  
BASSM 0C  
BSM 0B

For comparison with the RR-format instructions, the results of two RX-format instructions are also shown.

The format of the BAL instruction is:

Machine Format

| Op Code | R <sub>1</sub> | X <sub>2</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----------------|----------------|----------------|----------------|
| 45      | 5              | 0              | 6              | 000            |

Assembler Format

| Op Code | R <sub>1</sub> , D <sub>2</sub> (X <sub>2</sub> , B <sub>2</sub> ) |
|---------|--------------------------------------------------------------------|
| BAL     | 5,0(0,6)                                                           |

The BAS instruction has the same format, but the op code is 4D.

The BCR instruction specifies only one register:

Machine Format

| Op Code | M <sub>1</sub> | R <sub>2</sub> |
|---------|----------------|----------------|
| 07      | F              | 6              |

Assembler Format

| Op Code | M <sub>1</sub> , R <sub>2</sub> |
|---------|---------------------------------|
| BCR     | 15,6                            |

Assume that:

Register 5 contains BB BB BB BB.

Register 6 contains 82 46 8A CE.

PSW bits 32-63 contain

00 00 10 D6 (for 24-bit addressing).  
80 00 10 D6 (for 31-bit addressing).

Condition code is 01<sub>2</sub>.

Program mask is 1100<sub>2</sub>.

The effect of executing each instruction in turn is as follows:

**24-Bit Mode Initially**

| Instruction  | Register 5  | PSW (32-63) |
|--------------|-------------|-------------|
| Before       | BB BB BB BB | 00 00 10 D6 |
| BCR 15,6     | BB BB BB BB | 00 46 8A CE |
| BAL 5,0(0,6) | 9C 00 10 DA | 00 46 8A CE |
| BAS 5,0(0,6) | 00 00 10 DA | 00 46 8A CE |
| BALR 5,6     | 5C 00 10 D8 | 00 46 8A CE |
| BASR 5,6     | 00 00 10 D8 | 00 46 8A CE |
| BASSM 5,6    | 00 00 10 D8 | 82 46 8A CE |
| BSM 5,6      | 3B BB BB BB | 82 46 8A CE |

**31-Bit Mode Initially**

| Instruction  | Register 5  | PSW (32-63) |
|--------------|-------------|-------------|
| Before       | BB BB BB BB | 80 00 10 D6 |
| BCR 15,6     | BB BB BB BB | 82 46 8A CE |
| BAL 5,0(0,6) | 80 00 10 DA | 82 46 8A CE |
| BAS 5,0(0,6) | 80 00 10 DA | 82 46 8A CE |
| BALR 5,6     | 80 00 10 D8 | 82 46 8A CE |
| BASR 5,6     | 80 00 10 D8 | 82 46 8A CE |
| BASSM 5,6    | 80 00 10 D8 | 82 46 8A CE |
| BSM 5,6      | BB BB BB BB | 82 46 8A CE |

Note that a value of zero in the R<sub>2</sub> field of any of the RR-format instructions indicates that the branching function is not to be performed; it does not refer to register 0. Likewise, a value of zero in the R<sub>1</sub> field of the BSM instruction indicates that the old value of

PSW bit 32 is not to be saved and that register 0 is to be left unchanged. Register 0 can be designated by the  $R_1$  field of instructions BAL, BALR, BAS, BASR, and BASSM, however. In the RX-format branch instructions, branching occurs independent of whether there is a value of zero in the  $B_2$  field or  $X_2$  field of the instruction. However, when the field is zero, instead of using the contents of general register 0, a value of zero is used for that component of address generation.

**Programming Note:** It should be noted that execution of BAL in the 24-bit addressing mode results in bit 0 of register 5 being set to one. This is because the ILC for an RX-format instruction is 10. This is the only case in which bit zero of the return register does not correctly reflect the addressing mode of the caller. Thus, BSM may be used to return for BALR, BAS, BASR, and BASSM in both the 24-bit and the 31-bit addressing modes, but it cannot be used to return if the program was called by using BAL in the 24-bit addressing mode.

### Other BALR and BASR Examples

The BALR or BASR instruction with the  $R_2$  field set to zero may be used to load a register for use as a base register. For example, in the assembler language, the two statements:

```
BALR    15,0
USING   *,15
```

or

```
BASR    15,0
USING   *,15
```

indicate that the address of the next sequential instruction following the BALR or BASR instruction will be placed in register 15, and that the assembler may use register 15 as a base register until otherwise instructed. (The USING statement is an “assembler instruction” and is thus not a part of the object program.)

## BRANCH AND STACK (BAKR)

The semiprivileged BRANCH AND STACK instruction facilitates linkage between subroutines by saving status in a linkage-stack state entry (sometimes called a branch state entry to distinguish it from a program-call state entry). When BRANCH AND STACK has been used, the return from the called

program is made by means of the PROGRAM RETURN instruction. PROGRAM RETURN restores access registers 2-14, general registers 2-14, and the PSW with values saved in the state entry, except that it leaves the PER mask unchanged and sets the condition code to an unpredictable value. The use of BRANCH AND STACK is discussed in “Branching Using the Linkage Stack” on page 5-74.

BRANCH AND STACK can be used to perform a calling linkage, or it can be used at or near the entry point of the called program, depending on whether the  $R_1$  field of the instruction is zero or nonzero, respectively. If the  $R_1$  field is zero, bits 32-63 of the PSW saved in the state entry indicate the current addressing mode (24-bit or 31-bit) and the address of the next sequential instruction after the BRANCH AND STACK instruction or an EXECUTE instruction. If the  $R_1$  field is nonzero, bits 32-63 of the PSW saved in the state entry are set with a value generated from the contents of general register  $R_1$ : bit 32 of the PSW is set equal to bit 0 of the register, and bits 1-31 of the PSW are set with an address generated from bits 1-31 of the register under the control of bit 0 of the register. Bits 32-63 of the PSW saved in the state entry are referred to in the following examples as the return value.

The branch address for the instruction is generated from the contents of general register  $R_2$  under the control of the current addressing mode. Bit 0 of general register  $R_2$  does not affect the operation. If the  $R_2$  field of the instruction is zero, the operation is performed without branching.

In addition to saving a complete PSW (except with an unpredictable PER mask) in the state entry, BRANCH AND STACK saves the new value of bits 32-63 of the current PSW in the state entry. Bits 32-63 are referred to in the following examples as the branch value.

The following examples contain cases in which bit 32 of the current PSW is either zero or one (24-bit or 31-bit addressing) before BRANCH AND STACK is executed and in which bit 0 of the general register designated by a nonzero  $R_1$  or  $R_2$  field is either zero or one.

### BAKR Example 1

This example shows BAKR used in a calling program. BAKR performs a branch, and the return is to be to the next sequential instruction.

The format of the BAKR instruction is:

Machine Format

| Op Code | R <sub>1</sub> | R <sub>2</sub> |
|---------|----------------|----------------|
| B240    | 0              | 6              |

Assembler Format

Op Code R<sub>1</sub>,R<sub>2</sub>

BAKR 0,6

Assume four cases of initial values, as follows:

|    | PSW (32-63) | Register 6  |
|----|-------------|-------------|
| 1. | 00 00 10 D6 | 02 46 8A CE |
| 2. | 00 00 10 D6 | 82 46 8A CE |
| 3. | 80 00 10 D6 | 02 46 8A CE |
| 4. | 80 00 10 D6 | 82 46 8A CE |

The results in the four cases are as follows:

|    | Return Value | Branch Value and PSW (32-63) |
|----|--------------|------------------------------|
| 1. | 00 00 10 DA  | 00 46 8A CE                  |
| 2. | 00 00 10 DA  | 00 46 8A CE                  |
| 3. | 80 00 10 DA  | 82 46 8A CE                  |
| 4. | 80 00 10 DA  | 82 46 8A CE                  |

### BAKR Example 2

This example shows BAKR used in a called program. BAKR does not perform a branch, and the return is to be as specified in general register R<sub>1</sub>.

The format of the BAKR instruction is:

Machine Format

| Op Code | R <sub>1</sub> | R <sub>2</sub> |
|---------|----------------|----------------|
| B240    | 5              | 0              |

Assembler Format

Op Code R<sub>1</sub>,R<sub>2</sub>

BAKR 5,0

Assume four cases of initial values, as follows:

|    | Register 5  | PSW (32-63) |
|----|-------------|-------------|
| 1. | 04 00 10 D6 | 00 46 8A CE |
| 2. | 04 00 10 D6 | 82 46 8A CE |

3. 84 00 10 D6 00 46 8A CE
4. 84 00 10 D6 82 46 8A CE

The results in the four cases are as follows:

|    | Return Value | Branch Value and PSW (32-63) |
|----|--------------|------------------------------|
| 1. | 00 00 10 D6  | 00 46 8A D2                  |
| 2. | 00 00 10 D6  | 82 46 8A D2                  |
| 3. | 84 00 10 D6  | 00 46 8A D2                  |
| 4. | 84 00 10 D6  | 82 46 8A D2                  |

### BAKR Example 3

This example shows BAKR used in a called program. BAKR performs a branch, and the return is to be as specified in general register R<sub>1</sub>.

The format of the BAKR instruction is:

Machine Format

| Op Code | R <sub>1</sub> | R <sub>2</sub> |
|---------|----------------|----------------|
| B240    | 5              | 6              |

Assembler Format

Op Code R<sub>1</sub>,R<sub>2</sub>

BAKR 5,6

Assume eight cases of initial values, as follows:

|    | Register 5  | Register 6  | PSW (32-63) |
|----|-------------|-------------|-------------|
| 1. | 04 00 10 D6 | 06 99 99 00 | 00 46 8A CE |
| 2. | 04 00 10 D6 | 06 99 99 00 | 82 46 8A CE |
| 3. | 04 00 10 D6 | 86 99 99 00 | 00 46 8A CE |
| 4. | 04 00 10 D6 | 86 99 99 00 | 82 46 8A CE |
| 5. | 84 00 10 D6 | 06 99 99 00 | 00 46 8A CE |
| 6. | 84 00 10 D6 | 06 99 99 00 | 82 46 8A CE |
| 7. | 84 00 10 D6 | 86 99 99 00 | 00 46 8A CE |
| 8. | 84 00 10 D6 | 86 99 99 00 | 82 46 8A CE |

The results in the eight cases are as follows:

|    | Return Value | Branch Value and PSW (32-63) |
|----|--------------|------------------------------|
| 1. | 00 00 10 D6  | 00 99 99 00                  |
| 2. | 00 00 10 D6  | 86 99 99 00                  |
| 3. | 00 00 10 D6  | 00 99 99 00                  |
| 4. | 00 00 10 D6  | 86 99 99 00                  |
| 5. | 84 00 10 D6  | 00 99 99 00                  |
| 6. | 84 00 10 D6  | 86 99 99 00                  |
| 7. | 84 00 10 D6  | 00 99 99 00                  |
| 8. | 84 00 10 D6  | 86 99 99 00                  |

## BRANCH ON CONDITION (BC, BCR)

The BRANCH ON CONDITION instruction tests the condition code to see whether a branch should or should not occur. The branch occurs only if the current condition code corresponds to a one bit in a mask specified by the instruction.

| Condition Code | Instruction (Mask) Bit | Mask Value |
|----------------|------------------------|------------|
| 0              | 8                      | 8          |
| 1              | 9                      | 4          |
| 2              | 10                     | 2          |
| 3              | 11                     | 1          |

For example, assume that an ADD (A or AR) operation has been performed and that a branch to address 6050 is desired if the sum is zero or less (condition code is 0 or 1). Also assume:

Register 10 contains 00 00 50 00.

Register 11 contains 00 00 10 00.

The RX form of the instruction performs the required test (and branch if necessary) when written as:

Machine Format

| Op Code | M <sub>1</sub> | X <sub>2</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----------------|----------------|----------------|----------------|
| 47      | C              | B              | A              | 050            |

Assembler Format

Op Code M<sub>1</sub>, D<sub>2</sub> (X<sub>2</sub>, B<sub>2</sub>)

BC 12, X'50' (11, 10)

A mask of 12<sub>10</sub> means that there are ones in instruction bits 8 and 9 and zeros in bits 10 and 11, so that branching takes place when the condition code is either 0 or 1.

A mask of 15 would indicate a branch on any condition (an unconditional branch). A mask of zero would indicate that no branch is to occur (a no-operation).

(See also "Linkage Instructions (BAL, BALR, BAS, BASR, BASSM, BSM)" on page A-8 for an example of the BCR instruction.)

## BRANCH ON COUNT (BCT, BCTR)

The BRANCH ON COUNT instruction is often used to execute a program loop for a specified number of times. For example, assume that the following represents some lines of coding in an assembler-language program:

```

:
LUPE  AR   8,1
:
BACK  BCT  6,LUPE
:

```

where register 6 contains 00 00 00 03 and the address of LUPE is 6826. Assume that, in order to address this location, register 10 is used as a base register and contains 00 00 68 00.

The format of the BCT instruction is:

Machine Format

| Op Code | R <sub>1</sub> | X <sub>2</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----------------|----------------|----------------|----------------|
| 46      | 6              | 0              | A              | 026            |

Assembler Format

Op Code R<sub>1</sub>, D<sub>2</sub> (X<sub>2</sub>, B<sub>2</sub>)

BCT 6, X'26' (0, 10)

The effect of the coding is to execute three times the loop defined by the instructions labeled LUPE through BACK, while register 6 is decremented from three to zero.

## BRANCH ON INDEX HIGH (BXH)

### BXH Example 1

The BRANCH ON INDEX HIGH instruction is an index-incrementing and loop-controlling instruction that causes a branch whenever the sum of an index value and an increment value is greater than some compare value. For example, assume that:

Register 4 contains 00 00 00 8A = 138<sub>10</sub> = the index.

Register 6 contains 00 00 00 02 = 2<sub>10</sub> = the increment.

Register 7 contains 00 00 00 AA = 170<sub>10</sub> = the compare value.

Register 10 contains 00 00 71 30 = the branch address.

The format of the BXH instruction is:

Machine Format

| Op Code | R <sub>1</sub> | R <sub>3</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----------------|----------------|----------------|----------------|
| 86      | 4              | 6              | A              | 000            |

Assembler Format

Op Code R<sub>1</sub>,R<sub>3</sub>,D<sub>2</sub>(B<sub>2</sub>)

BXH 4,6,0(10)

When the instruction is executed, first the contents of register 6 are added to register 4, second the sum is compared with the contents of register 7, and third the decision whether to branch is made. After execution:

Register 4 contains 00 00 00 8C = 140<sub>10</sub>.

Registers 6 and 7 are unchanged.

Since the new value in register 4 is not yet greater than the value in register 7, the branch to address 7130 is not taken. Repeated use of the instruction will eventually cause the branch to be taken when the value in register 4 reaches 172<sub>10</sub>.

## BXH Example 2

When the register used to contain the increment is odd, that register also becomes the compare-value register. The following assembler-language subroutine illustrates how this may be used to search a table.

| Table   |         |
|---------|---------|
| 2 Bytes | 2 Bytes |
| ARG1    | FUNCT1  |
| ARG2    | FUNCT2  |
| ARG3    | FUNCT3  |
| ARG4    | FUNCT4  |
| ARG5    | FUNCT5  |
| ARG6    | FUNCT6  |

Assume that:

Register 8 contains the search argument.

Register 9 contains the width of the table in bytes (00 00 00 04).

Register 10 contains the length of the table in bytes (00 00 00 18).

Register 11 contains the starting address of the table.

Register 14 contains the return address to the main program.

As the following subroutine is executed, the argument in register 8 is successively compared with the arguments in the table, starting with argument 6 and working backward to argument 1. If an equality is found, the corresponding function replaces the argument in register 8. If an equality is not found, zero replaces the argument in register 8.

```

SEARCH    LNR  9,9
NOTEQUAL  BXH  10,9,LOOP
NOTFOUND  SR   8,8
          BCR  15,14
LOOP      CH   8,0(10,11)
          BC   7,NOTEQUAL
          LH   8,2(10,11)
          BCR  15,14

```

The first instruction (LNR) causes the value in register 9 to be made negative. After execution of this instruction, register 9 contains FF FF FF FC = -4<sub>10</sub>. Considering the case when no equality is found, the BXH instruction will be executed seven times. Each time BXH is executed, a value of -4 is added to register 10, thus reducing the value in register 10 by 4. The new value in register 10 is compared with the -4 value in register 9. The branch is taken each time until the value in register 10 is -4. Then the branch is not taken, and the SR instruction sets register 8 to zero.

## BRANCH ON INDEX LOW OR EQUAL (BXLE)

The BRANCH ON INDEX LOW OR EQUAL instruction performs the same operation as BRANCH ON INDEX HIGH, except that branching occurs when the sum is lower than or equal to (instead of higher than) the compare value. As the instruction which increments and tests an index value in a program loop, BXLE is useful at the end of the loop and BXH at the beginning. The following assembler-language routines illustrate loops with BXLE.

### BXLE Example 1

Assume that a group of ten 32-bit signed binary integers are stored at consecutive locations, starting at location GROUP. The integers are to be added together, and the sum is to be stored at location SUM.

|        |          |                    |
|--------|----------|--------------------|
| SR     | 5,5      | Set sum to zero    |
| LA     | 6,GROUP  | Load first address |
| SR     | 7,7      | Set index to zero  |
| LA     | 8,4      | Load increment 4   |
| LA     | 9,39     | Load compare value |
| LOOP A | 5,0(7,6) | Add integer to sum |
| BXLE   | 7,8,LOOP | Test end of loop   |
| ST     | 5,SUM    | Store sum          |

The two-instruction loop contains an ADD (A) instruction which adds each integer to the contents of general register 5. The ADD instruction uses the contents of general register 7 as an index value to modify the starting address obtained from register 6. Next, BXLE increments the index value by 4, the increment previously loaded into register 8, and compares it with the compare value in register 9, the odd register of this even-odd pair. The compare value was previously set to 39, which is one less than the number of bytes in the data area; this is also the address, relative to the starting address, of the rightmost byte of the last integer to be added. When the last integer has been added, BXLE increments the index value to the next relative address (40), which is found to be greater than the compare value (39) so that no branching takes place.

### BXLE Example 2

The technique illustrated in Example 1 is restricted to loops containing instructions in the RX instruction format. That format allows both a base register and an index register to be specified (double indexing).

For instructions in other formats, where an index register cannot be specified, the previous technique may be modified by having the address itself serve as the index value in a BXLE instruction and by using as the compare value the address of the last byte rather than its relative address. The base register then provides the address directly at each iteration of the loop, and it is not necessary to specify a second register to hold the index value (single indexing).

In the following example, an AND (NI) instruction in the SI instruction format sets to zero the rightmost bit of each of the same group of integers as in Example

1, thus making all of them even. The  $I_2$  field of the NI instruction contains the byte X'FE', which consists of seven ones and a zero. That byte is ANDed into byte 3, the rightmost byte, of each of the integers in turn.

|         |            |                    |
|---------|------------|--------------------|
| LA      | 6,GROUP    | Load first address |
| LA      | 8,4        | Load increment 4   |
| LA      | 9,GROUP+39 | Load compare value |
| LOOP NI | 3(6),X'FE' | AND immediate      |
| BXLE    | 6,8,LOOP   | Test end of loop   |

The technique shown in Example 2 does not work, however, on an ESA/370 system when it is in the 31-bit addressing mode and the data is located at the rightmost end of a 31-bit address space. In this case, the compare value would be set to  $2^{31}-1$ , which is the largest possible 32-bit signed binary value. The reason the technique does not work is that the BXLE and BXH instructions treat their operands as 32-bit signed binary integers. When the address in general register 6 reaches the value  $2^{31}-4$ , BXLE increments it to a value that is interpreted as  $-2^{31}$ , rather than  $2^{31}$ , and the comparison remains low, which causes looping to continue indefinitely.

This situation can be avoided by not allowing data areas to extend to the rightmost location in a 31-bit address space or by using other techniques; these may include double indexing when possible, as in Example 1, or starting at the end and stepping downward through the data area with a negative increment.

## COMPARE AND FORM CODEWORD (CFC)

See "Sorting Instructions" on page A-53.

## COMPARE HALFWORD (CH)

The COMPARE HALFWORD instruction compares a 16-bit signed binary integer in storage with the contents of a register. For example, assume that:

Register 4 contains FF FF 80 00 =  $-32,768_{10}$ .

Register 13 contains 00 01 60 50.

Storage locations 16080-16081 contain 8000 =  $-32,768_{10}$ .

When the instruction:

## Machine Format

| Op Code | R <sub>1</sub> | X <sub>2</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----------------|----------------|----------------|----------------|
| 49      | 4              | 0              | D              | 030            |

## Assembler Format

Op Code R<sub>1</sub>,D<sub>2</sub>(X<sub>2</sub>,B<sub>2</sub>)

CH 4,X'30'(0,13)

is executed, the contents of locations 16080-16081 are fetched, expanded to 32 bits (the sign bit is propagated to the left), and compared with the contents of register 4. Because the two numbers are equal, condition code 0 is set.

## COMPARE LOGICAL (CL, CLC, CLI, CLR)

The COMPARE LOGICAL instruction differs from the signed-binary comparison instructions (C, CH, CR) in that all quantities are handled as unsigned binary integers or as unstructured data.

### CLC Example

The COMPARE LOGICAL (CLC) instruction can be used to perform the byte-by-byte comparison of storage fields up to 256 bytes in length. For example, assume that the following two fields of data are in storage:

Field 1

|      |    |    |    |    |    |    |    |    |    |    |    |  |  |  |  |      |
|------|----|----|----|----|----|----|----|----|----|----|----|--|--|--|--|------|
| 1886 |    |    |    |    |    |    |    |    |    |    |    |  |  |  |  | 1891 |
| D1   | D6 | C8 | D5 | E2 | D6 | D5 | 6B | C1 | 4B | C2 | 4B |  |  |  |  |      |

Field 2

|      |    |    |    |    |    |    |    |    |    |    |    |  |  |  |  |      |
|------|----|----|----|----|----|----|----|----|----|----|----|--|--|--|--|------|
| 1900 |    |    |    |    |    |    |    |    |    |    |    |  |  |  |  | 190B |
| D1   | D6 | C8 | D5 | E2 | D6 | D5 | 6B | C1 | 4B | C3 | 4B |  |  |  |  |      |

Also assume:

Register 9 contains 00 00 18 80.

Register 7 contains 00 00 19 00.

Execution of the instruction:

## Machine Format

| Op Code | L  | B <sub>1</sub> | D <sub>1</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----|----------------|----------------|----------------|----------------|
| D5      | 0B | 9              | 006            | 7              | 000            |

## Assembler Format

Op Code D<sub>1</sub>(L,B<sub>1</sub>),D<sub>2</sub>(B<sub>2</sub>)

CLC 6(12,9),0(7)

sets condition code 1, indicating that the contents of field 1 are lower in value than the contents of field 2.

Because the collating sequence of the EBCDIC code is determined simply by a logical comparison of the bits in the code, the CLC instruction can be used to collate EBCDIC-coded fields. For example, in EBCDIC, the above two data fields are:

Field 1: JOHNSON,A.B.

Field 2: JOHNSON,A.C.

Condition code 1 indicates that JOHNSON,A.B. should precede JOHNSON,A.C. for the fields to be in alphabetic sequence.

### CLI Example

The COMPARE LOGICAL (CLI) instruction compares a byte from the instruction stream with a byte from storage. For example, assume that:

Register 10 contains 00 00 17 00.

Storage location 1703 contains 7E.

Execution of the instruction:

## Machine Format

| Op Code | I <sub>2</sub> | B <sub>1</sub> | D <sub>1</sub> |
|---------|----------------|----------------|----------------|
| 95      | AF             | A              | 003            |

## Assembler Format

Op Code D<sub>1</sub>(B<sub>1</sub>),I<sub>2</sub>

CLI 3(10),X'AF'

sets condition code 1, indicating that the first operand (the quantity in main storage) is lower than the second (immediate) operand.

### CLR Example

Assume that:

Register 4 contains 00 00 00 01 = 1.

Register 7 contains FF FF FF FF =  $2^{32} - 1$ .

Execution of the instruction:

Machine Format

| Op Code | R <sub>1</sub> | R <sub>2</sub> |
|---------|----------------|----------------|
| 15      | 4              | 7              |

Assembler Format

| Op Code | R <sub>1</sub> , R <sub>2</sub> |
|---------|---------------------------------|
| CLR     | 4, 7                            |

sets condition code 1. Condition code 1 indicates that the first operand is lower than the second.

If, instead, the signed-binary comparison instruction COMPARE (CR) had been executed, the contents of register 4 would have been interpreted as +1 and the contents of register 7 as -1. Thus, the first operand would have been higher, so that condition code 2 would have been set.

## COMPARE LOGICAL CHARACTERS UNDER MASK (CLM)

The COMPARE LOGICAL CHARACTERS UNDER MASK (CLM) instruction provides a means of comparing bytes selected from a general register to a contiguous field of bytes in storage. The M<sub>3</sub> field of the CLM instruction is a four-bit mask that selects zero to four bytes from a general register, each mask bit corresponding, left to right, to a register byte. In the comparison, the register bytes corresponding to ones in the mask are treated as a contiguous field. The operation proceeds left to right. For example, assume that:

Storage locations 10200-10202 contain F0 BC 7B.

Register 12 contains 00 01 00 00.

Register 6 contains F0 BC 5C 7B.

Execution of the instruction:

Machine Format

| Op Code | R <sub>1</sub> | M <sub>3</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----------------|----------------|----------------|----------------|
| BD      | 6              | D              | C              | 200            |

Assembler Format

| Op Code | R <sub>1</sub> , M <sub>3</sub> , D <sub>2</sub> (B <sub>2</sub> ) |
|---------|--------------------------------------------------------------------|
| CLM     | 6, B'1101', X'200' (12)                                            |

causes the following comparison:

|                       |    |    |    |    |
|-----------------------|----|----|----|----|
| Register 6:           | F0 | BC | 5C | 7B |
| Mask M <sub>3</sub> : | 1  | 1  | 0  | 1  |
|                       | -- | -- |    | -- |

Because the selected bytes are equal, condition code 0 is set.

## COMPARE LOGICAL LONG (CLCL)

The COMPARE LOGICAL LONG instruction is used to compare two operands in storage, byte by byte. Each operand can be of any length. Two even-odd pairs of general registers (four registers in all) are used to locate the operands and to control the execution of the CLCL instruction, as illustrated in the following diagram. The first register of each pair must be an even register, and it contains the storage address of an operand. The odd register of each pair contains the length of the operand it covers, and the leftmost byte of the second-operand odd register contains a padding byte which is used to extend the shorter operand, if any, to the same length as the longer operand.

The following illustrates the assignment of registers in the 24-bit addressing mode:

In the 31-bit addressing mode, the operand addresses would be in bit positions 1-31 of the even registers shown above.

Since the CLCL instruction may be interrupted during execution, the interrupting program must preserve the contents of the four registers for use when the instruction is resumed.

The following instructions set up two register pairs to control a text-string comparison. For example, assume:

Operand 1  
 Address: 20800<sub>16</sub>  
 Length: 100<sub>10</sub>

Operand 2  
 Address: 20A00<sub>16</sub>  
 Length: 132<sub>10</sub>

Padding Byte  
 Address: 20003<sub>16</sub>  
 Length: 1  
 Value: 40<sub>16</sub>

Register 12 contains 00 02 00 00.

The setup instructions are:

|     |                 |                                                             |
|-----|-----------------|-------------------------------------------------------------|
| LA  | 4,X'800'(12)    | Set register 4 to start of first operand                    |
| LA  | 5,100           | Set register 5 to length of first operand                   |
| LA  | 8,X'A00'(12)    | Set register 8 to start of second operand                   |
| LA  | 9,132           | Set register 9 to length of second operand                  |
| ICM | 9,B'1000',3(12) | Insert padding byte in leftmost byte position of register 9 |

Register pair 4,5 defines the first operand. Bits 8-31 of register 4 contain the storage address of the start of an EBCDIC text string, and bits 8-31 of register 5 contain the length of the string, in this case 100 bytes.

Register pair 8,9 defines the second operand, with bits 8-31 of register 8 containing the starting location of the second operand and bits 8-31 of register 9 containing the length of the second operand, in this case 132 bytes. Bits 0-7 of register 9 contain an EBCDIC blank character (X'40') to pad the shorter operand. In this example, the padding byte is used in the first operand, after the 100th byte, to compare with the remaining bytes in the second operand.

With the register pairs thus set up, the format of the CLCL instruction is:

Machine Format

|         |       |       |
|---------|-------|-------|
| Op Code | $R_1$ | $R_2$ |
| 0F      | 4     | 8     |

Assembler Format

|         |            |
|---------|------------|
| Op Code | $R_1, R_2$ |
| CLCL    | 4,8        |

When this instruction is executed, the comparison starts at the left end of each operand and proceeds to the right. The operation ends as soon as an inequality is detected or the end of the longer operand is reached.

If this CLCL instruction is interrupted after 60 bytes have compared equal, the operand lengths in registers 5 and 9 will have been decremented to 40 and 72, respectively. The operand addresses in registers 4 and 8 will have been incremented to X'2083C' and X'20A3C'; the leftmost byte of registers 4 and 8 will have been set to zero. The padding byte X'40' remains in register 9. When the CLCL instruction is reexecuted with these register contents, the comparison resumes at the point of interruption.

Now, assume that the instruction is interrupted after 110 bytes. That is, the first 100 bytes of the second operand have compared equal to the first operand, and the next 10 bytes of the second operand have compared equal to the padding byte (blank). The residual operand lengths in registers 5 and 9 are 0 and 22, respectively, and the operand addresses in registers 4 and 8 are X'20864' (the value when the first operand was exhausted) and X'20A6E' (the current value for the second operand).

When the comparison ends, the condition code is set to 0, 1, or 2, depending on whether the first operand

is equal to, less than, or greater than the second operand, respectively.

When the operands are unequal, the addresses in registers 4 and 8 indicate the bytes that caused the mismatch.

## COMPARE LOGICAL STRING (CLST)

The COMPARE LOGICAL STRING instruction is used to compare a first operand designated by general register  $R_1$  and a second operand designated by general register  $R_2$ . The comparison is made left to right, byte by byte, until unequal bytes are compared, an ending character specified in general register 0 is encountered in either operand, or a CPU-determined number of bytes have been compared. The condition code is set to 0 if the two operands are equal, to 1 if the first operand is low, to 2 if the second operand is low, or to 3 if a CPU-determined number of bytes have been compared. If the ending character is found in both operands simultaneously, the operands are equal. If it is found in only one operand, that operand is low.

When condition code 1 or 2 is set, the addresses of the last bytes processed in the first and second operands are placed in general registers  $R_1$  and  $R_2$ , respectively. These are the addresses of unequal bytes in the two operands, or they are the address of an ending character in one operand and of the byte in the corresponding byte position in the other operand. When condition code 3 is set, the addresses of the next bytes to be processed are placed in the registers. When condition code 0 is set, the contents of the registers remain unchanged.

Following are examples of first and second operands beginning at decimal locations 1000 and 2000, respectively. The addresses in general registers  $R_1$  and  $R_2$  are 1000 and 2000, respectively. The ending character in general register 0 is 00 hex (as in the C programming language). The values of the operand bytes are shown in hex, and the resulting condition code and final contents of general registers  $R_1$  and  $R_2$  are shown.

### Example 1

```
1000      2000
C1 C2 C3 00  C1 C2 C3 00

CC: 0; (R1): 1000; (R2): 2000
```

### Example 2

```
1000      2000
40 40 40 C1  40 40 40 C2

CC: 1; (R1): 1003; (R2): 2003
```

### Example 3

```
1000      2000
40 40 40 C2  40 40 40 C1

CC: 2; (R1): 1003; (R2): 2003
```

### Example 4

```
1000      2000
C1 C2 C3 00  C1 C2 C3 C4

CC: 1; (R1): 1003; (R2): 2003
```

### Example 5

```
1000      2000
C1 C2 C3 C4  C1 C2 C3 00

CC: 2; (R1): 1003; (R2): 2003
```

### Example 6

Assuming that the CPU-determined number of bytes compared is 256:

```
1000      1256 2000      2256
40 .. 40 00  40 .. 40 00

CC: 3; (R1): 1256; (R2): 2256
```

### Example 7

```
1000      2000
00 40 40 40  40 40 40 40

CC: 1; (R1): 1000; (R2): 2000
```

### Example 8

```
1000      2000
40 40 40 40  00 40 40 40

CC: 2; (R1): 1000; (R2): 2000
```

### Example 9

```
1000      2000
00 40 40 40  00 40 40 40

CC: 0; (R1): 1000; (R2): 2000
```

## CONVERT TO BINARY (CVB)

The CONVERT TO BINARY instruction converts an eight-byte, signed-packed-decimal number into a signed binary integer and loads the result into a gen-

eral register. After the conversion operation is completed, the number is in the proper form for use as an operand in signed binary arithmetic. For example, assume:

Storage locations 7608-760F contain a decimal number in the signed-packed-decimal format: 00 00 00 00 25 59 4C (+25,594).

The contents of register 7 are not significant.

Register 13 contains 00 00 76 00.

The format of the conversion instruction is:

Machine Format

| Op Code | R <sub>1</sub> | X <sub>2</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----------------|----------------|----------------|----------------|
| 4F      | 7              | 0              | D              | 008            |

Assembler Format

| Op Code | R <sub>1</sub> , D <sub>2</sub> (X <sub>2</sub> , B <sub>2</sub> ) |
|---------|--------------------------------------------------------------------|
| CVB     | 7, 8(0, 13)                                                        |

After the instruction is executed, register 7 contains 00 00 63 FA.

## CONVERT TO DECIMAL (CVD)

The CONVERT TO DECIMAL instruction is the opposite of the CONVERT TO BINARY instruction. CVD converts a signed binary integer in a register to signed-packed-decimal number and stores the eight-byte result. For example, assume:

Register 1 contains the signed binary integer: 00 00 0F 0F.

Register 13 contains 00 00 76 00.

The format of the instruction is:

Machine Format

| Op Code | R <sub>1</sub> | X <sub>2</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----------------|----------------|----------------|----------------|
| 4E      | 1              | 0              | D              | 008            |

Assembler Format

| Op Code | R <sub>1</sub> , D <sub>2</sub> (X <sub>2</sub> , B <sub>2</sub> ) |
|---------|--------------------------------------------------------------------|
| CVD     | 1, 8(0, 13)                                                        |

After the instruction is executed, storage locations 7608-760F contain 00 00 00 00 03 85 5C (+3855).

The plus sign generated is the preferred plus sign, 1100<sub>2</sub>.

## DIVIDE (D, DR)

The DIVIDE instruction divides the dividend in an even-odd register pair by the divisor in a register or in storage. Since the instruction assumes the dividend to be 64 bits long, it is important first to extend a 32-bit dividend on the left with bits equal to the sign bit. For example, assume that:

Storage locations 3550-3553 contain 00 00 08 DE = 2270<sub>10</sub> (the dividend).

Storage locations 3554-3557 contain 00 00 00 32 = 50<sub>10</sub> (the divisor).

The initial contents of registers 6 and 7 are not significant.

Register 8 contains 00 00 35 50.

The following assembler-language statements load the registers properly and perform the divide operation:

| Statement     | Comments                                                                            |
|---------------|-------------------------------------------------------------------------------------|
| L 6, 0(0, 8)  | Places 00 00 08 DE into register 6.                                                 |
| SRDA 6, 32(0) | Shifts 00 00 08 DE into register 7.<br>Register 6 is filled with zeros (sign bits). |
| D 6, 4(0, 8)  | Performs the division.                                                              |

The machine format of the above DIVIDE instruction is:

Machine Format

| Op Code | R <sub>1</sub> | X <sub>2</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----------------|----------------|----------------|----------------|
| 5D      | 6              | 0              | 8              | 004            |

After the instructions listed above are executed:

Register 6 contains 00 00 00 14 = 20<sub>10</sub> = the remainder.

Register 7 contains 00 00 00 2D = 45<sub>10</sub> = the quotient.

Note that if the dividend had not been first placed in register 6 and shifted into register 7, register 6 might not have been filled with the proper dividend-sign bits (zeros in this example), and the DIVIDE instruction might not have given the expected results.

## EXCLUSIVE OR (X, XC, XI, XR)

When the Boolean operator EXCLUSIVE OR is applied to two bits, the result is one when either, but not both, of the two bits is one; otherwise, the result is zero. When two bytes are EXCLUSIVE ORed, each pair of bits is handled separately; there is no connection from one bit position to another. The following is an example of the EXCLUSIVE OR of two bytes:

First-operand byte: 0011 0101<sub>2</sub>

Second-operand byte: 0101 1100<sub>2</sub>

Result byte: 0110 1001<sub>2</sub>

### XC Example

The EXCLUSIVE OR (XC) instruction can be used to exchange the contents of two areas in storage without the use of an intermediate storage area. For example, assume two three-byte fields in storage:

Field 1      359              358  

|    |    |    |
|----|----|----|
| 00 | 17 | 90 |
|----|----|----|

Field 2      360              362  

|    |    |    |
|----|----|----|
| 00 | 14 | 01 |
|----|----|----|

Execution of the instruction (assume that register 7 contains 00 00 03 58):

#### Machine Format

| Op Code | L  | B <sub>1</sub> | D <sub>1</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----|----------------|----------------|----------------|----------------|
| D7      | 02 | 7              | 001            | 7              | 008            |

#### Assembler Format

Op Code    D<sub>1</sub>(L,B<sub>1</sub>),D<sub>2</sub>(B<sub>2</sub>)

XC        1(3,7),8(7)

Field 1 is EXCLUSIVE ORed with field 2 as follows:

Field 1: 00000000 00010111 10010000<sub>2</sub> = 00 17 90<sub>16</sub>

Field 2: 00000000 00010100 00000001<sub>2</sub> = 00 14 01<sub>16</sub>

Result: 00000000 00000011 10010001<sub>2</sub> = 00 03 91<sub>16</sub>

The result replaces the former contents of field 1. Condition code 1 is set to indicate a nonzero result.

Now, execution of the instruction:

#### Machine Format

| Op Code | L  | B <sub>1</sub> | D <sub>1</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----|----------------|----------------|----------------|----------------|
| D7      | 02 | 7              | 008            | 7              | 001            |

#### Assembler Format

Op Code    D<sub>1</sub>(L,B<sub>1</sub>),D<sub>2</sub>(B<sub>2</sub>)

XC        8(3,7),1(7)

produces the following result:

Field 1: 00000000 00000011 10010001<sub>2</sub> = 00 03 91<sub>16</sub>

Field 2: 00000000 00010100 00000001<sub>2</sub> = 00 14 01<sub>16</sub>

Result: 00000000 00010111 10010000<sub>2</sub> = 00 17 90<sub>16</sub>

The result of this operation replaces the former contents of field 2. Field 2 now contains the original value of field 1. Condition code 1 is set to indicate a nonzero result.

Lastly, execution of the instruction:

#### Machine Format

| Op Code | L  | B <sub>1</sub> | D <sub>1</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----|----------------|----------------|----------------|----------------|
| D7      | 02 | 7              | 001            | 7              | 008            |

#### Assembler Format

Op Code    D<sub>1</sub>(L,B<sub>1</sub>),D<sub>2</sub>(B<sub>2</sub>)

XC        1(3,7),8(7)

produces the following result:

Field 1: 00000000 00000011 10010001<sub>2</sub> = 00 03 91<sub>16</sub>

Field 2: 00000000 00010111 10010000<sub>2</sub> = 00 17 90<sub>16</sub>

Result: 00000000 00010100 00000001<sub>2</sub> = 00 14 01<sub>16</sub>

The result of this operation replaces the former contents of field 1. Field 1 now contains the original value of field 2. Condition code 1 is set to indicate a nonzero result.

## XI Example

A frequent use of the EXCLUSIVE OR (XI) instruction is to invert a bit (change a zero bit to a one or a one bit to a zero). For example, assume that storage location 8082 contains  $0110\ 1001_2$ . To invert the leftmost and rightmost bits without affecting any of the other bits, the following instruction can be used (assume that register 9 contains  $00\ 00\ 80\ 80$ ):

### Machine Format

| Op Code | $I_2$ | $B_1$ | $D_1$ |
|---------|-------|-------|-------|
| 97      | 81    | 9     | 002   |

### Assembler Format

Op Code     $D_1(B_1), I_2$

---

XI        2(9), X'81'

When the instruction is executed, the byte in storage is EXCLUSIVE ORed with the immediate byte (the  $I_2$  field of the instruction):

Location 8082:     $0110\ 1001_2$   
 Immediate byte:    $1000\ 0001_2$

---

Result:             $1110\ 1000_2$

The resulting byte is stored back in location 8082. Condition code 1 is set to indicate a nonzero result.

### Notes:

1. With the XC instruction, fields up to 256 bytes in length can be exchanged.
2. With the XR instruction, the contents of two registers can be exchanged.
3. Because the X instruction operates storage to register only, an exchange cannot be made solely by the use of X.
4. A field EXCLUSIVE ORed with itself is cleared to zeros.
5. For additional examples of the use of EXCLUSIVE OR, see "Hexadecimal-Floating-Point-Number Conversion" on page A-44.

## EXECUTE (EX)

The EXECUTE instruction causes one *target instruction* in main storage to be executed out of sequence

without actually branching to the target instruction. Unless the  $R_1$  field of the EXECUTE instruction is zero, bits 8-15 of the target instruction are ORed with bits 56-63 of the  $R_1$  register before the target instruction is executed. Thus, EXECUTE may be used to supply the length field for an SS instruction without modifying the SS instruction in storage. For example, assume that a MOVE (MVC) instruction is the target that is located at address 3820, with a format as follows:

### Machine Format

| Op Code | L  | $B_1$ | $D_1$ | $B_2$ | $D_2$ |
|---------|----|-------|-------|-------|-------|
| D2      | 00 | C     | 003   | D     | 000   |

### Assembler Format

Op Code     $D_1(L, B_1), D_2(B_2)$

---

MVC        3(1,12), 0(13)

where register 12 contains  $00\ 00\ 89\ 13$  and register 13 contains  $00\ 00\ 90\ A0$ .

Further assume that at storage address 5000, the following EXECUTE instruction is located:

### Machine Format

| Op Code | $R_1$ | $X_2$ | $B_2$ | $D_2$ |
|---------|-------|-------|-------|-------|
| 44      | 1     | 0     | A     | 000   |

### Assembler Format

Op Code     $R_1, D_2(X_2, B_2)$

---

EX        1, 0(0,10)

where register 10 contains  $00\ 00\ 38\ 20$  and register 1 contains  $00\ 0F\ F0\ 03$ .

When the instruction at 5000 is executed, the rightmost byte of register 1 is ORed with the second byte of the target instruction:

Instruction byte:     $0000\ 0000_2 = 00$   
 Register byte:        $0000\ 0011_2 = 03$

---

Result:                 $0000\ 0011_2 = 03$

causing the instruction at 3820 to be executed as if it originally were:

## Machine Format

| Op Code | L  | B <sub>1</sub> | D <sub>1</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----|----------------|----------------|----------------|----------------|
| D2      | 03 | C              | 003            | D              | 000            |

## Assembler Format

Op Code D<sub>1</sub>(L,B<sub>1</sub>),D<sub>2</sub>(B<sub>2</sub>)

MVC 3(4,12),0(13)

However, after execution:

Register 1 is unchanged.

The instruction at 3820 is unchanged.

The contents of the four bytes starting at location 90A0 have been moved to the four bytes starting at location 8916.

The CPU next executes the instruction at address 5004 (PSW bits 104-127 contain 00 50 04).

## FIND LEFTMOST ONE (FLOGR)

FIND LEFTMOST ONE may be used to locate free objects, the availability of which is tracked in a hierarchical bit map.

In the following example, the hierarchical bit map consists of multiple levels of bits, each level having 64 times the number of bits as the next lower-numbered level. This example shows four levels, mapping a total of 16M objects, however additional levels may be added to manage larger numbers of objects.

The highest-numbered bit map level (L3 in this illustration) represents the availability of individual objects, for example, records or pages. A one bit indicates that the object is available, and a zero bit means that the object is not available.

In lower-numbered bit map levels (L0, L1, and L2 in this illustration), a bit position corresponds to a doubleword in the next higher-numbered level. When a bit in a lower-numbered bit map level is one, at least one bit of the corresponding doubleword in the higher-level is one. When a bit in a lower-number bit

map level is zero, no bits in the corresponding higher-level doubleword are one.

An example of using FIND LEFTMOST ONES to quickly locate the next available lowest-numbered object, as mapped by such a hierarchical bit map, is shown below. Upon completion, at the label "FOUND", general register 15 contains the number of the located object. If no objects are available, the code branches to the label "NOTFND".

```

LA 15,0          Zero accumulator
LA 9,OFFSET      Point to table
LA 10,4          Load increment
LA 11,ENDOFF-1   Load compare value
FIND LGR 7,15     Copy accum. to R7
      ALGF 7,0(,9) Add # DWs to bits
      SLLG 7,7,3  Get byte offset
      LG 1,BITS(7) Get DW to test
      FLOGR 0,1   Find leftmost one
      BZ NOTFND   No one bits found
      SLLG 15,15,6 Times # bits in DW
      AGR 15,0    Add bit just found
      BXLEG 9,10,FIND Do for each level
FOUND STG 1,BITS(7) Update changed bit
      ...
NOTFND [Any instruction]
```

```

OFFSET DC A((L0-BITS)/8) Offset to level 0
        DC A((L1-BITS)/8) Offset to level 1
        DC A((L2-BITS)/8) Offset to level 2
        DC A((L3-BITS)/8) Offset to level 3
ENDOFF EQU *
```

```

BITS DS 0D          Start of bit map
L0 DS FD            -L0 (64 objects)
L1 DS 64FD          -L1 (4K objects)
L2 DS (64*64)FD     -L2 (256K objects)
L3 DS (64*64*64)FD -L3 (16M objects)
```

This code sequence shows the zeroing of the found bit with the STORE (STG) instruction at the label "FOUND". Proper maintenance of such a hierarchical bit map requires that when all bits of a doubleword become zeros, the corresponding bit in the next lower-numbered level is set to zeros. Similarly, when adding a free object to the highest level, the corresponding bits in lower-numbered levels must be set to one. These maintenance functions are not shown.

Note, in a multiprocessing environment, access to the bit map is assumed to be serialized for the duration of the update process.

## INSERT CHARACTERS UNDER MASK (ICM)

The INSERT CHARACTERS UNDER MASK (ICM) instruction may be used to replace all or selected bytes in a general register with bytes from storage and to set the condition code to indicate the value of the inserted field.

For example, if it is desired to insert a three-byte address from FIELD A into register 5 and leave the leftmost byte of the register unchanged, assume:

### Machine Format

| Op Code | R <sub>1</sub> | M <sub>3</sub> | S <sub>2</sub> |
|---------|----------------|----------------|----------------|
| BF      | 5              | 7              | * * * *        |

### Assembler Format

Op Code R<sub>1</sub>,M<sub>3</sub>,S<sub>2</sub>

ICM 5,B'0111',FIELD A

FIELD A: FE DC BA  
 Register 5 (before): 12 34 56 78  
 Register 5 (after): 12 FE DC BA  
 Condition code (after): 1 (leftmost bit of inserted field is one)

As another example:

### Machine Format

| Op Code | R <sub>1</sub> | M <sub>3</sub> | S <sub>2</sub> |
|---------|----------------|----------------|----------------|
| BF      | 6              | 9              | * * * *        |

### Assembler Format

Op Code R<sub>1</sub>,M<sub>3</sub>,S<sub>2</sub>

ICM 6,B'1001',FIELD B

FIELDB: 12 34  
 Register 6 (before): 00 00 00 00  
 Register 6 (after): 12 00 00 34  
 Condition code (after): 2 (inserted field is nonzero with leftmost zero bit)

When the mask field contains 1111, the ICM instruction produces the same result as LOAD (L) (provided that the indexing capability of the RX format is not

needed), except that ICM also sets the condition code. The condition-code setting is useful when an all-zero field (condition code 0) or a leftmost one bit (condition code 1) is used as a flag.

## LOAD (L, LR)

The LOAD instruction takes four bytes from storage or from a general register and place them unchanged into a general register. For example, assume that the four bytes starting with location 21003 are to be loaded into register 10. Initially:

Register 5 contains 00 02 00 00.

Register 6 contains 00 00 10 03.

The contents of register 10 are not significant.

Storage locations 21003-21006 contain 00 00 AB CD.

To load register 10, the RX form of the instruction can be used:

### Machine Format

| Op Code | R <sub>1</sub> | X <sub>2</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----------------|----------------|----------------|----------------|
| 58      | A              | 5              | 6              | 000            |

### Assembler Format

Op Code R<sub>1</sub>,D<sub>2</sub>(X<sub>2</sub>,B<sub>2</sub>)

L 10,0(5,6)

After the instruction is executed, register 10 contains 00 00 AB CD.

## LOAD ADDRESS (LA)

The LOAD ADDRESS instruction provides a convenient way to place a nonnegative binary integer up to 4095<sub>10</sub> in a register without first defining a constant and then using it as an operand. For example, the following instruction places the number 2048<sub>10</sub> in register 1:

### Machine Format

| Op Code | R <sub>1</sub> | X <sub>2</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----------------|----------------|----------------|----------------|
| 41      | 1              | 0              | 0              | 800            |

### Assembler Format

Op Code  $R_1, D_2(X_2, B_2)$

LA 1,2048(0,0)

The LOAD ADDRESS instruction can also be used to increment a register by an amount up to  $4095_{10}$  specified in the  $D_2$  field. Depending on the addressing mode, only the rightmost 24 or 31 bits of the sum are retained, however. The leftmost bits of the 32-bit result are set to zeros. For example, assume that register 5 contains 00 12 34 56.

The instruction:

### Machine Format

| Op Code | $R_1$ | $X_2$ | $B_2$ | $D_2$ |
|---------|-------|-------|-------|-------|
| 41      | 5     | 0     | 5     | 00A   |

### Assembler Format

Op Code  $R_1, D_2(X_2, B_2)$

LA 5,10(0,5)

adds 10 (decimal) to the contents of register 5 as follows:

Register 5 (old): 00 12 34 56  
 $D_2$  field: 00 00 00 0A

Register 5 (new): 00 12 34 60

The register may be specified as either  $B_2$  or  $X_2$ . Thus, the instruction LA 5,10(5,0) produces the same result.

As the most general example, the instruction LA 6,10(5,4) forms the sum of three values: the contents of register 4, the contents of register 5, and a displacement of 10 and places the 24-bit or 31-bit sum with zeros appended on the left in register 6.

## LOAD HALFWORD (LH)

The LOAD HALFWORD instruction places unchanged a halfword from storage into the right half of a register. The left half of the register is loaded with zeros or ones according to the sign (leftmost bit) of the halfword.

For example, assume that the two bytes in storage locations 1803-1804 are to be loaded into register 6. Also assume:

The contents of register 6 are not significant.

Register 14 contains 00 00 18 03.

Locations 1803-1804 contain 00 20.

The instruction required to load the register is:

### Machine Format

| Op Code | $R_1$ | $X_2$ | $B_2$ | $D_2$ |
|---------|-------|-------|-------|-------|
| 48      | 6     | 0     | E     | 000   |

### Assembler Format

Op Code  $R_1, D_2(X_2, B_2)$

LH 6,0(0,14)

After the instruction is executed, register 6 contains 00 00 00 20. If locations 1803-1804 had contained a negative number, for example, A7 B6, a minus sign would have been propagated to the left, giving FF FF A7 B6 as the final result in register 6.

## MOVE (MVC, MVI)

### MVC Example

The MOVE (MVC) instruction can be used to move data from one storage location to another. For example, assume that the following two fields are in storage:

Also assume:

Register 1 contains 00 00 20 48.

Register 2 contains 00 00 38 40.

With the following instruction, the first eight bytes of field 2 replace the first eight bytes of field 1:

| Op Code | L  | B <sub>1</sub> | D <sub>1</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----|----------------|----------------|----------------|----------------|
| D2      | 07 | 1              | 000            | 2              | 000            |

MVC       $0(8,1), 0(2)$ 

| Field | 2048 |    |    |    |    |    |    |    |    |    |    | 2052 |
|-------|------|----|----|----|----|----|----|----|----|----|----|------|
| 1     | F1   | F2 | F3 | F4 | F5 | F6 | F7 | F8 | C9 | CA | CB |      |

|    |    |    |    |    |    |    |    |    |
|----|----|----|----|----|----|----|----|----|
| 00 | F1 | F2 | F3 | F4 | F5 | F6 | F7 | F8 |
|----|----|----|----|----|----|----|----|----|

MVC  $1(8,11), 0(11)$ 

| Op Code | I <sub>2</sub> | B <sub>1</sub> | D <sub>1</sub> |
|---------|----------------|----------------|----------------|
| 92      | 5B             | 1              | 000            |

| Field | 2048 |    |    |    |    |    |    |    |    | 2052 |    |
|-------|------|----|----|----|----|----|----|----|----|------|----|
| 1     | C1   | C2 | C3 | C4 | C5 | C6 | C7 | C8 | C9 | CA   | CB |

|       |      |    |      |
|-------|------|----|------|
| Field | 3840 |    | 3848 |
| 2     | F1   | F2 | F3   |
|       | F4   | F5 | F6   |
|       | F7   | F8 | F9   |

A-25

## Machine Format

| Op Code | L  | B <sub>1</sub> | D <sub>1</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----|----------------|----------------|----------------|----------------|
| E8      | 07 | 1              | 000            | 2              | 007            |

## Assembler Format

Op Code D<sub>1</sub>(L,B<sub>1</sub>),D<sub>2</sub>(B<sub>2</sub>)

MVCIN 0(8,1),7(2)

After the instruction is executed, field 1 becomes:

| Field | 2048 |    |    |    |    |    |    |    |    |    |    | 2052 |
|-------|------|----|----|----|----|----|----|----|----|----|----|------|
| 1     | F8   | F7 | F6 | F5 | F4 | F3 | F2 | F1 | C9 | CA | CB |      |

Field 2 is unchanged.

**Note:** This example uses the same general registers, storage locations, and original values as the first example for MVC. For MVCIN, the second-operand address must designate the rightmost byte of the field to be moved, in this case location 3847. This is accomplished by means of the 7 in the D<sub>2</sub> field of the instruction.

## MOVE LONG (MVCL)

The MOVE LONG (MVCL) instruction can be used for moving data in storage as in the first example of the MVC instruction, provided that the two operands do not overlap. MVCL differs from MVC in that the address and length of each operand are specified in an even-odd pair of general registers. Consequently, MVCL can be used to move more than 256 bytes of data with one instruction. As an example, assume:

Register 2 contains 00 0A 00 00.

Register 3 contains 00 00 08 00.

Register 8 contains 00 06 00 00.

Register 9 contains 00 00 08 00.

Execution of the instruction:

## Machine Format

| Op Code | R <sub>1</sub> | R <sub>2</sub> |
|---------|----------------|----------------|
| 0E      | 8              | 2              |

## Assembler Format

Op Code R<sub>1</sub>,R<sub>2</sub>

MVCL 8,2

moves 2,048<sub>10</sub> bytes from locations A0000-A07FF to locations 60000-607FF. Assuming that the CPU is in the 24-bit addressing mode, bits 8-31 of registers 2 and 8 are incremented by 800<sub>16</sub>, and bits 0-7 of registers 2 and 8 are set to zeros. Bits 8-31 of registers 3 and 9 are decremented to zero. Condition code 0 is set to indicate that the operand lengths are equal.

If register 3 had contained F0 00 04 00, only the 1,024<sub>10</sub> bytes from locations A0000-A03FF would have been moved to locations 60000-603FF. The remaining locations 60400-607FF of the first operand would have been filled with 1,024 copies of the padding byte X'F0', as specified by the leftmost byte of register 3. Bits 8-31 of register 2 would have been incremented by 400<sub>16</sub>, bits 8-31 of register 8 would have been incremented by 800<sub>16</sub>, and bits 0-7 of registers 2 and 8 would have been set to zeros. Bits 8-31 of registers 3 and 9 would still have been decremented to zero. Condition code 2 would have been set to indicate that the first operand was longer than the second.

The technique for setting a field to zeros that is illustrated in the second example of MVC cannot be used with MVCL. If the registers were set up to attempt such an operation with MVCL, no data movement would take place and condition code 3 would indicate destructive overlap.

Instead, MVCL may be used to clear a storage area to zeros as follows. Assume register 8 and 9 are set up as before. Register 3 contains only zeros, specifying zero length for the second operand and a zero padding byte. Register 2 is not used to access storage, and its contents are not significant. Executing the instruction MVCL 8,2 causes locations 60000-607FF to be filled with zeros. Bits 8-31 of register 8 are incremented by 800<sub>16</sub>, and bits 0-7 of registers 2 and 8 are set to zeros. Bits 8-31 of register 9 are decremented to zero, and condition code 2 is set to indicate that the first operand is longer than the second.

## MOVE NUMERICS (MVN)

Two related instructions, MOVE NUMERICS and MOVE ZONES, may be used with decimal data in the zoned format to operate separately on the rightmost

four bits (the numeric bits) and the leftmost four bits (the zone bits) of each byte. Both are similar to MOVE (MVC), except that MOVE NUMERICS moves only the numeric bits and MOVE ZONES moves only the zone bits.

To illustrate the operation of the MOVE NUMERICS instruction, assume that the following two fields are in storage:

Also assume:

Register 14 contains 00 00 70 90.

Register 15 contains 00 00 70 40.

After the instruction:

Machine Format

| Op Code | L  | B <sub>1</sub> | D <sub>1</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----|----------------|----------------|----------------|----------------|
| D1      | 03 | F              | 001            | E              | 000            |

Assembler Format

Op Code D<sub>1</sub>(L, B<sub>1</sub>), D<sub>2</sub>(B<sub>2</sub>)

MVN 1(4, 15), 0(14)

is executed, field B becomes:

The numeric bits of the bytes at locations 7090-7093 have been stored in the numeric bits of the bytes at locations 7041-7044. The contents of locations 7090-7093 and 7045-7046 are unchanged.

## MOVE STRING (MVST)

The MOVE STRING instruction is used to move a second operand designated by general register R<sub>2</sub> to a first-operand location designated by general register R<sub>1</sub>. The movement is made left to right until an ending character specified in general register 0 has been moved or a CPU-determined number of bytes

have been moved. The condition code is set to 1 if the ending character was moved or to 3 if a CPU-determined number of bytes were moved.

When condition code 1 is set, the address of the ending character in the first operand is placed in general register R<sub>1</sub>, and the contents of general register R<sub>2</sub> remain unchanged. When condition code 3 is set, the address of the next byte to be processed in the first and second operands is placed in general registers R<sub>1</sub> and R<sub>2</sub>, respectively.

Following is an example program that sets string A equal to the concatenation of string B followed by string C, where the length of each of strings B and C is unknown, and the end of each of strings B and C is indicated by an ending character of 00 hex (as in the C programming language). The program is not written for execution in the access-register mode.

```

L      4, STRAADR
L      5, STRBADR
SR      0, 0
LOOP1  MVST  4, 5
BC      1, LOOP1
L      5, STRCADR
LOOP2  MVST  4, 5
BC      1, LOOP2
[Any instruction]
```

## MOVE WITH OFFSET (MVO)

MOVE WITH OFFSET may be used to shift a signed-packed-decimal number an odd number of digit positions or to concatenate a sign to an unsigned-packed-decimal number.

Assume that the three-byte unsigned-packed-decimal number in storage locations 4500-4502 is to be moved to locations 5600-5603 and given the sign of the signed-packed-decimal number ending at location 5603. Also assume:

Register 12 contains 00 00 56 00.

Register 15 contains 00 00 45 00.

Storage locations 5600-5603 contain 77 88 99 0C.

Storage locations 4500-4502 contain 12 34 56.

After the instruction:

## Machine Format

| Op Code | L <sub>1</sub> | L <sub>2</sub> | B <sub>1</sub> | D <sub>1</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----------------|----------------|----------------|----------------|----------------|----------------|
| F1      | 3              | 2              | C              | 000            | F              | 000            |

## Assembler Format

Op Code D<sub>1</sub>(L<sub>1</sub>,B<sub>1</sub>),D<sub>2</sub>(L<sub>2</sub>,B<sub>2</sub>)

MV0 0(4,12),0(3,15)

is executed, the storage locations 5600-5603 contain 01 23 45 6C. Note that the second operand is extended on the left with one zero to fill out the first-operand field.

## MOVE ZONES (MVZ)

The MOVE ZONES instruction can operate on overlapping or nonoverlapping fields, as can the instructions MOVE (MVC) and MOVE NUMERICS. When operating on nonoverlapping fields, MOVE ZONES works like the MOVE NUMERICS instruction (see its example), except that MOVE ZONES moves only the zone bits of each byte. To illustrate the use of MOVE ZONES with overlapping fields, assume that the following data field is in storage:

|     |    |    |    |    |    |     |
|-----|----|----|----|----|----|-----|
| 800 |    |    |    |    |    | 805 |
| F1  | C2 | F3 | C4 | F5 | C6 |     |

Also assume that register 15 contains 00 00 08 00. The instruction:

## Machine Format

| Op Code | L  | B <sub>1</sub> | D <sub>1</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----|----------------|----------------|----------------|----------------|
| D3      | 04 | F              | 001            | F              | 000            |

## Assembler Format

Op Code D<sub>1</sub>(L,B<sub>1</sub>),D<sub>2</sub>(B<sub>2</sub>)

MVZ 1(5,15),0(15)

propagates the zone bits from the byte at address 800 through the entire field, so that the field becomes:

|     |     |    |    |    |    |
|-----|-----|----|----|----|----|
| 800 | 805 |    |    |    |    |
| F1  | F2  | F3 | F4 | F5 | F6 |

## MULTIPLY (M, MR)

Assume that a number in register 5 is to be multiplied by the contents of a four-byte field at address 3750. Initially:

The contents of register 4 are not significant.

Register 5 contains 00 00 00 9A = 154<sub>10</sub> = the multiplicand.

Register 11 contains 00 00 06 00.

Register 12 contains 00 00 30 00.

Storage locations 3750-3753 contain 00 00 00 83 = 131<sub>10</sub> = the multiplier.

The instruction required for performing the multiplication is:

## Machine Format

| Op Code | R <sub>1</sub> | X <sub>2</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----------------|----------------|----------------|----------------|
| 5C      | 4              | B              | C              | 150            |

## Assembler Format

Op Code R<sub>1</sub>,D<sub>2</sub>(X<sub>2</sub>,B<sub>2</sub>)

M 4,X'150'(11,12)

After the instruction is executed, the product is in the register pair 4 and 5:

Register 4 contains 00 00 00 00.

Register 5 contains 00 00 4E CE = 20,174<sub>10</sub>.

Storage locations 3750-3753 are unchanged.

The RR format of the instruction can be used to square the number in a register. Assume that register 7 contains 00 01 00 05. The contents of register 6 are not significant. The instruction:

## Machine Format

| Op Code | R <sub>1</sub> | R <sub>2</sub> |
|---------|----------------|----------------|
| 1C      | 6              | 7              |

## Assembler Format

Op Code R<sub>1</sub>,R<sub>2</sub>

MR 6,7

multiplies the number in register 7 by itself and places the result in the pair of registers 6 and 7:

Register 6 contains 00 00 00 01.

Register 7 contains 00 0A 00 19.

## MULTIPLY HALFWORD (MH)

The MULTIPLY HALFWORD instruction is used to multiply the contents of a register by a two-byte field in storage. For example, assume that:

Register 11 contains 00 00 00 15 =  $21_{10}$  = the multiplicand.

Register 14 contains 00 00 01 00.

Register 15 contains 00 00 20 00.

Storage locations 2102-2103 contain FF D9 = - $39_{10}$  = the multiplier.

The instruction:

Machine Format

| Op Code | R <sub>1</sub> | X <sub>2</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----------------|----------------|----------------|----------------|
| 4C      | B              | E              | F              | 002            |

Assembler Format

Op Code R<sub>1</sub>, D<sub>2</sub>(X<sub>2</sub>, B<sub>2</sub>)

MH 11, 2(14, 15)

multiplies the two numbers. The product, FF FF FC CD = - $819_{10}$ , replaces the original contents of register 11.

Only the rightmost 32 bits of a product are stored in a register; any significant bits on the left are lost. No program interruption occurs on overflow.

## OR (O, OC, OI, OR)

When the Boolean operator OR is applied to two bits, the result is one when either bit is one; otherwise, the result is zero. When two bytes are ORed, each pair of bits is handled separately; there is no connection from one bit position to another. The following is an example of ORing two bytes:

First-operand byte: 0011 0101<sub>2</sub>

Second-operand byte: 0101 1100<sub>2</sub>

Result byte: 0111 1101<sub>2</sub>

## OI Example

A frequent use of the OR instruction is to set a particular bit to one. For example, assume that storage location 4891 contains 0100 0010<sub>2</sub>. To set the rightmost bit of this byte to one without affecting the other bits, the following instruction can be used (assume that register 8 contains 00 00 48 90):

Machine Format

| Op Code | I <sub>2</sub> | B <sub>1</sub> | D <sub>1</sub> |
|---------|----------------|----------------|----------------|
| 96      | 01             | 8              | 001            |

Assembler Format

Op Code D<sub>1</sub>(B<sub>1</sub>), I<sub>2</sub>

OI 1(8), X'01'

When this instruction is executed, the byte in storage is ORed with the immediate byte (the I<sub>2</sub> field of the instruction):

Location 4891: 0100 0010<sub>2</sub>

Immediate byte: 0000 0001<sub>2</sub>

Result: 0100 0011<sub>2</sub>

The resulting byte with bit 7 set to one is stored back in location 4891. Condition code 1 is set.

## PACK (PACK)

Assume that storage locations 1000-1003 contain the following zoned-decimal number that is to be converted to a signed-packed-decimal number and left in the same location:

|              | 1000 |    | 1003  |
|--------------|------|----|-------|
| Zoned number | F1   | F2 | F3 C4 |

Also assume that register 12 contains 00 00 10 00. After the instruction:

Machine Format

| Op Code | L <sub>1</sub> | L <sub>2</sub> | B <sub>1</sub> | D <sub>1</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----------------|----------------|----------------|----------------|----------------|----------------|
| F2      | 3              | 3              | C              | 000            | C              | 000            |

## Assembler Format

Op Code  $D_1(L_1, B_1), D_2(L_2, B_2)$

PACK 0(4,12),0(4,12)

is executed, the result in locations 1000-1003 is in the signed-packed-decimal format:

Signed-packed number

| 1000 | 1001 | 1002 | 1003 |
|------|------|------|------|
| 00   | 01   | 23   | 4C   |

### Notes:

1. This example illustrates the operation of PACK when the first- and second-operand fields overlap completely.
2. During the operation, the second operand was extended on the left with zeros.

## ROTATE THEN EXCLUSIVE OR SELECTED BITS

The following example illustrates the use of ROTATE THEN EXCLUSIVE OR SELECTED BITS to determine if the access-control bits of a page's storage-protection key match the key in the PSW. In this example, only the condition code is set; the result is not placed in the first-operand register.

LAY 9,BLOCK Point to storage block.  
IVSK 14,9 Insert key into bits 56-63.  
EPSW 4,0 Extract PSW key (bits 40-43).  
RXSBG 4,14,128+40,43,16 Compare keys.

On completion, the condition code will be set to zero if the PSW key matches the access-control bits in the storage key of page addressed by general register 9. Condition code 1 will be set if the keys do not match.

## ROTATE THEN INSERT SELECTED BITS

1. The following example illustrates the use of ROTATE THEN INSERT SELECTED BITS to extract the various DAT-table indices of a virtual address contained in general register 8. This example shows the use of the zero-remaining-bits control to set the remaining bits of the result registers to zero.

The virtual address in general register 8 is assumed to be 123456789ABCDEF0 hex.

RISBG 1,8,53,128+63,11 Get reg. 1st index.  
RISBG 2,8,53,128+63,22 Get reg. 2nd index.  
RISBG 3,8,53,128+63,33 Get reg. 3rd index.  
RISBG 4,8,53,128+63,44 Get segment index.  
RISBG 5,8,56,128+63,52 Get page index.  
RISBG 6,8,52,128+63,0 Get byte index.

The condition code following each RISBG is 2. On completion, general registers 1-6 contain the region-first index, region-second index, region-third index, segment index, page index, and byte index, respectively, as follows:

GR1: 0000000000000091 (RFX)  
GR2: 0000000000000515 (RSX)  
GR3: 00000000000004F1 (RTX)  
GR4: 00000000000001AB (SX)  
GR5: 00000000000000CD (PX)  
GR6: 0000000000000EF0 (BX)

2. The following example illustrates shifting a 64-bit value to the left by  $L$  bits:

RISBG  $R_1, R_2, 0, X'80' + 63 - L, L$

3. The following example illustrates shifting a 32-bit value to the right by  $R$  bits and setting the left-most 32 bits to zero:

RISBG  $R_1, R_2, 32 + R, X'80' + 63, -R$

4. The following example illustrates zeroing bits  $S$  through  $E$  of general register 3.

RISBG 3,3,mod64( $E+1$ ),128+mod64( $S-1$ ),0

*Mod64* represents a modulo function which effectively ANDs the value in parentheses with 3F hex.

## ROTATE THEN OR SELECTED BITS

The following example illustrates the use of ROTATE THEN OR SELECTED BITS to rotate and combine selected bits of general registers 6 and 8.

LG 6,=X'004C487040CF4600'  
LG 8,=X'C07FAF37FC968280'  
ROSBG 6,8,8,54,32

On completion, condition code 1 is set, and general register 6 is as follows:

```
GR6: 00DECAF0C0FFEE00
```

Note that only bits 8-54 of the registers are ORed; bits 0-7 and 55-63 of general register 6 are not modified.

## SEARCH STRING (SRST)

The SEARCH STRING instruction is used to search a second operand designated by general register  $R_2$  for a character specified in general register 0. The length of the second operand is known — the address of the first byte after the second operand is in general register  $R_1$ .

When the specified character is found, condition code 1 is set, the address of the character is placed in general register  $R_1$ , and the contents of general register  $R_2$  remain unchanged. When the address of the next second-operand byte to be examined equals the address in general register  $R_1$ , condition code 2 is set, and the contents of general register  $R_1$  and  $R_2$  remain unchanged. When a CPU-determined number of second-operand bytes have been examined, condition code 3 is set, the address of the next byte to be processed in the second operand is placed in general register  $R_2$ , and the contents of general register  $R_1$  remain unchanged.

### SRST Example 1

Following is an example program that determines the end of string A, as indicated by an ending character equal to 00 hex (as in the C programming language), and then determines the address of the first character equal to C1 hex in the string. The program is based on the assumption that the second operand does not begin at location 0 or wrap around in storage, and, therefore, condition code 2 will not be set by the first SEARCH STRING instruction because of the address in general register 0. The program is not written for execution in the access-register mode.

```
L      5,STRAADR
SR      0,0
LOOP1 SRST 0,5
BC      1,LOOP1
L      5,STRAADR
LR      4,0
LA      0,X'C1'
```

```
LOOP2 SRST 4,5
BC      1,LOOP2
BC      2,NOTFND
FOUND [Any instruction]
...
NOTFND [Any instruction]
```

### SRST Example 2

Following is an example program that determines the address of the first character equal to C1 hex in the string A whose length is known. The program is not written for execution in the access-register mode.

```
L      5,STRAADR
L      4,STRALEN
AR      4,5
LA      0,X'C1'
LOOP1 SRST 4,5
BC      1,LOOP1
BC      2,NOTFND
FOUND [Any instruction]
...
NOTFND [Any instruction]
```

In this example, the value in STRALEN may be a length that either does or does not include an ending character at the end of the string, provided that the ending character is not the character for which the search is made.

## SHIFT LEFT DOUBLE (SLDA)

The SHIFT LEFT DOUBLE instruction shifts the 63 numeric bits of an even-odd register pair to the left, leaving the sign bit unchanged. Thus, the instruction performs an algebraic left shift of a 64-bit signed binary integer.

For example, if the contents of registers 2 and 3 are:

```
00 7F 0A 72   FE DC BA 98 =
00000000 01111111 00001010 01110010
11111110 11011100 10111010 100110002
```

The instruction:

Machine Format

| Op Code | $R_1$ | $B_2$ | $D_2$ |
|---------|-------|-------|-------|
| 8F      | 2     | ////  | 0     |
|         |       |       | 01F   |

### Assembler Format

Op Code  $R_1, D_2(B_2)$

SLDA 2,31(0)

results in registers 2 and 3 both being left-shifted 31 bit positions, so that their new contents are:

7F 6E 5D 4C 00 00 00 00 =  
01111111 01101110 01011101 01001100  
00000000 00000000 00000000 00000000<sub>2</sub>

Because significant bits are shifted out of bit position 1 of register 2, overflow is indicated by setting condition code 3, and, if the fixed-point-overflow mask bit in the PSW is one, a fixed-point-overflow program interruption occurs.

## SHIFT LEFT SINGLE (SLA)

The SHIFT LEFT SINGLE instruction is similar to SHIFT LEFT DOUBLE, except that it shifts only the 31 numeric bits of a single register. Therefore, this instruction performs an algebraic left shift of a 32-bit signed binary integer.

For example, if the contents of register 2 are:

00 7F 0A 72 = 00000000 01111111 00001010 01110010<sub>2</sub>

The instruction:

### Machine Format

| Op Code | $R_1$ | $B_2$ | $D_2$ |
|---------|-------|-------|-------|
| 8B      | 2     | ////  | 008   |

### Assembler Format

Op Code  $R_1, D_2(B_2)$

SLA 2,8(0)

results in register 2 being shifted left eight bit positions so that its new contents are:

7F 0A 72 00 = 01111111 00001010 01110010 00000000<sub>2</sub>

Condition code 2 is set to indicate that the result is greater than zero.

If a left shift of nine places had been specified, a significant bit would have been shifted out of bit position 1. Condition code 3 would have been set to

indicate this overflow and, if the fixed-point-overflow mask bit in the PSW were one, a fixed-point overflow interruption would have occurred.

## STORE CHARACTERS UNDER MASK (STCM)

STORE CHARACTERS UNDER MASK (STCM) may be used to place selected bytes from a register into storage. For example, if it is desired to store a three-byte address from general register 8 into location FIELD3, assume:

### Machine Format

| Op Code | $R_1$ | $M_3$ | $S_2$   |
|---------|-------|-------|---------|
| BE      | 8     | 7     | * * * * |

### Register Format

Op Code  $R_1, M_3, S_2$

STCM 8,B'0111',FIELD3

Register 8: 12 34 56 78  
FIELD3 (before): not significant  
FIELD3 (after): 34 56 78

As another example:

### Machine Format

| Op Code | $R_1$ | $M_3$ | $S_2$   |
|---------|-------|-------|---------|
| BE      | 9     | 5     | * * * * |

### Register Format

Op Code  $R_1, M_3, S_2$

STCM 9,B'0101',FIELD2

Register 9: 01 23 45 67  
FIELD2 (before): not significant  
FIELD2 (after): 23 67

## STORE MULTIPLE (STM)

Assume that the contents of general registers 14, 15, 0, and 1 are to be stored in consecutive four-byte fields starting with location 4050 and that:

Register 14 contains 00 00 25 63.

Register 15 contains 00 01 27 36.

Register 0 contains 12 43 00 62.

Register 1 contains 73 26 12 57.

Register 6 contains 00 00 40 00.

The initial contents of locations 4050-405F are not significant.

The STORE MULTIPLE instruction allows the use of just one instruction to store the contents of the four registers:

#### Machine Format

| Op Code | R <sub>1</sub> | R <sub>3</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----------------|----------------|----------------|----------------|
| 90      | E              | 1              | 6              | 050            |

#### Assembler Format

Op Code R<sub>1</sub>, R<sub>3</sub>, D<sub>2</sub>(B<sub>2</sub>)

STM 14, 1, X'50' (6)

After the instruction is executed:

Locations 4050-4053 contain 00 00 25 63.

Locations 4054-4057 contain 00 01 27 36.

Locations 4058-405B contain 12 43 00 62.

Locations 405C-405F contain 73 26 12 57.

## TEST UNDER MASK (TM)

The TEST UNDER MASK instruction examines selected bits of a byte and sets the condition code accordingly. For example, assume that:

Storage location 9999 contains FB.

Register 7 contains 00 00 99 90.

Assume the instruction to be:

#### Machine Format

| Op Code | I <sub>2</sub> | B <sub>1</sub> | D <sub>1</sub> |
|---------|----------------|----------------|----------------|
| 91      | C3             | 7              | 009            |

#### Assembler Format

Op Code D<sub>1</sub>(B<sub>1</sub>), I<sub>2</sub>

TM 9(7), B'11000011'

The instruction tests only those bits of the byte in storage for which the mask bits are ones:

FB = 1111 1011<sub>2</sub>

Mask = 1100 0011<sub>2</sub>

Test = 11xx xx11<sub>2</sub>

Condition code 3 is set: all selected bits in the test result are ones. (The bits marked "x" are ignored.)

If location 9999 had contained B9, the test would have been:

B9 = 1011 1001<sub>2</sub>

Mask = 1100 0011<sub>2</sub>

Test = 10xx xx01<sub>2</sub>

Condition code 1 is set: the selected bits are both zeros and ones.

If location 9999 had contained 3C, the test would have been:

3C = 0011 1100<sub>2</sub>

Mask = 1100 0011<sub>2</sub>

Test = 00xx xx00<sub>2</sub>

Condition code 0 is set: all selected bits are zeros.

**Note:** Storage location 9999 remains unchanged.

## TRANSLATE (TR)

The TRANSLATE instruction can be used to translate data from any character code to any other desired code, provided that each character code consists of eight bits or fewer. An appropriate translation table is required in storage.

In the following example, EBCDIC code is translated to ASCII code. The first step is to create a 256-byte table in storage locations 1000-10FF. This table contains the characters of the ASCII code in the sequence of the binary representation of the EBCDIC code; that is, the ASCII representation of a

character is placed in storage at the starting address of the table plus the binary value of the EBCDIC representation of the same character.

For simplicity, the example shows only the part of the table containing the decimal digits:

|      |    |    |    |    |    |    |    |      |    |
|------|----|----|----|----|----|----|----|------|----|
| 10F0 |    |    |    |    |    |    |    | 10F9 |    |
| 30   | 31 | 32 | 33 | 34 | 35 | 36 | 37 | 38   | 39 |

Assume that the four-byte field at storage location 2100 contains the EBCDIC code for the digits 1984:

Locations 2100-2103 contain F1 F9 F8 F4.

Register 12 contains 00 00 21 00.

Register 15 contains 00 00 10 00.

As the instruction:

Machine Format

|         |    |                |                |                |                |
|---------|----|----------------|----------------|----------------|----------------|
| Op Code | L  | B <sub>1</sub> | D <sub>1</sub> | B <sub>2</sub> | D <sub>2</sub> |
| DC      | 03 | C              | 000            | F              | 000            |

Assembler Format

Op Code D<sub>1</sub>(L, B<sub>1</sub>), D<sub>2</sub>(B<sub>2</sub>)

TR 0(4, 12), 0(15)

is executed, the binary value of each EBCDIC byte is added to the starting address of the table, and the resulting address is used to fetch an ASCII byte:

Table starting address: 1000

First EBCDIC byte: F1

Address of ASCII byte: 10F1

After execution of the instruction:

Locations 2100-2103 contain 31 39 38 34.

Thus, the ASCII code for the digits 1984 has replaced the EBCDIC code in the four-byte field at storage location 2100.

## TRANSLATE AND TEST (TRT)

The TRANSLATE AND TEST instruction can be used to scan a data field for characters with a special meaning. To indicate which characters have a special

meaning, a table similar to the one used for the TRANSLATE instruction is set up, except that zeros in the table indicate characters without any special meaning and nonzero values indicate characters with a special meaning.

Figure A-4 on page A-34 has been set up to distinguish alphameric characters (A to Z and 0 to 9) from blanks, certain special symbols, and all other characters which are considered invalid. EBCDIC coding is assumed. The 256-byte table is assumed stored at locations 2000-20FF.

|     | 0  | 1  | 2  | 3  | 4  | 5  | 6  | 7  | 8  | 9  | A  | B  | C  | D  | E  | F  |
|-----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 200 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 |
| 201 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 |
| 202 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 |
| 203 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 |
| 204 | 04 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 08 | 40 | 0C | 10 | 40 |
| 205 | 14 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 18 | 1C | 20 | 40 | 40 |
| 206 | 24 | 28 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 2C | 40 | 40 | 40 | 40 |
| 207 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 30 | 34 | 38 | 3C | 40 |
| 208 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 |
| 209 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 |
| 20A | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 |
| 20B | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 | 40 |
| 20C | 40 | 00 | 00 | 00 | 00 | 00 | 00 | 00 | 00 | 00 | 40 | 40 | 40 | 40 | 40 | 40 |
| 20D | 40 | 00 | 00 | 00 | 00 | 00 | 00 | 00 | 00 | 00 | 40 | 40 | 40 | 40 | 40 | 40 |
| 20E | 40 | 40 | 00 | 00 | 00 | 00 | 00 | 00 | 00 | 00 | 40 | 40 | 40 | 40 | 40 | 40 |
| 20F | 00 | 00 | 00 | 00 | 00 | 00 | 00 | 00 | 00 | 00 | 40 | 40 | 40 | 40 | 40 | 40 |

**Note:** If the character codes in the statement being translated occupy a range smaller than 00 through FF<sub>16</sub>, a table of fewer than 256 bytes can be used.

Figure A-4. Translate and Test Table

The table entries for the alphameric characters in EBCDIC are 00; thus, the letter A (code C1) corresponds to byte location 20C1, which contains 00.

The 15 special symbols have nonzero entries from 04<sub>16</sub> to 3C<sub>16</sub> in increments of 4. Thus, the blank (code 40) has the entry 04<sub>16</sub>, the period (code 4B) has the entry 08<sub>16</sub>, and so on.

All other table positions have the entry 40<sub>16</sub> to indicate an invalid character.

The table entries are chosen so that they may be used to select one of a list of 16 words containing

addresses of different routines to be entered for each special symbol or invalid character encountered during the scan.

Assume that this list of 16 branch addresses is stored at locations 3004-3043.

Starting at storage location CA80, there is the following sequence of 21<sub>10</sub> EBCDIC characters, where "b" stands for a blank.

Locations CA80-CA94:  
UNPKbPROUT(9),WORD(5)

Also assume:

Register 1 contains 00 00 CA 7F.

Register 2 contains 00 00 30 00.

Register 15 contains 00 00 20 00.

As the instruction:

Machine Format

| Op Code | L  | B <sub>1</sub> | D <sub>1</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----|----------------|----------------|----------------|----------------|
| DD      | 14 | 1              | 001            | F              | 000            |

Assembler Format

Op Code D<sub>1</sub>(L,B<sub>1</sub>),D<sub>2</sub>(B<sub>2</sub>)

TRT 1(21,1),0(15)

is executed, the value of the first source byte, the EBCDIC code for the letter U, is added to the starting address of the table to produce the address of the table entry to be examined:

|                        |      |
|------------------------|------|
| Table starting address | 2000 |
| First source byte (U)  | E4   |
| <hr/>                  |      |
| Address of table entry | 20E4 |

Because zeros were placed in storage location 20E4, no special action occurs. The operation continues with the second and subsequent source bytes until it reaches the blank in location CA84. When this symbol is reached, its value is added to the starting address of the table, as usual:

|                        |      |
|------------------------|------|
| Table starting address | 2000 |
| Source byte (blank)    | 40   |
| <hr/>                  |      |
| Address of table entry | 2040 |

Because location 2040 contains a nonzero value, the following actions occur:

The address of the source byte, 00CA84, is placed in the rightmost 24 bits of register 1.

The table entry, 04, is placed in the rightmost eight bits of register 2, which now contains 00 00 30 04.

Condition code 1 is set (scan not completed).

The TRANSLATE AND TEST instruction may be followed by instructions to branch to the routine at the address found at location 3004, which corresponds to the blank character encountered in the scan. When this routine is completed, program control may return to the TRANSLATE AND TEST instruction to continue the scan, except that the length must first be adjusted for the characters already scanned.

For this purpose, the TRANSLATE AND TEST may be executed by the use of an EXECUTE instruction, which supplies the length specification from a general register. In this way, a complete statement scan can be performed with a single TRANSLATE AND TEST instruction used repeatedly by means of EXECUTE, and without modifying any instructions in storage. In the example, after the first execution of TRANSLATE AND TEST, register 1 contains the address of the last source byte translated. It is then a simple matter to subtract this address from the address of the last source byte (CA94) to produce a length specification. This length minus one is placed in the register that is referenced as the R<sub>1</sub> field of the EXECUTE instruction. (Note that the length code in the machine format is one less than the total number of bytes in the field.) The second-operand address of the EXECUTE instruction points to the TRANSLATE AND TEST instruction, which is the same as illustrated above, except for the length (L) which is set to zero.

## UNPACK (UNPK)

Assume that storage locations 2501-2502 contain a signed-packed-decimal number that is to be unpacked and placed in storage locations 1000-1004. Also assume:

Register 12 contains 00 00 10 00.

Register 13 contains 00 00 25 00.

Storage locations 2501-2502 contain 12 3D.

The initial contents of storage locations 1000-1004 are not significant.

After the instruction:

#### Machine Format

| Op Code | L <sub>1</sub> | L <sub>2</sub> | B <sub>1</sub> | D <sub>1</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----------------|----------------|----------------|----------------|----------------|----------------|
| F3      | 4              | 1              | C              | 000            | D              | 001            |

#### Assembler Format

Op Code D<sub>1</sub>(L<sub>1</sub>,B<sub>1</sub>),D<sub>2</sub>(L<sub>2</sub>,B<sub>2</sub>)

UNPK 0(5,12),1(2,13)

is executed, the storage locations 1000-1004 contain F0 F0 F1 F2 D3.

## UPDATE TREE (UPT)

See "Sorting Instructions" on page A-53.

## Decimal Instructions

(See Chapter 8, "Decimal Instructions" for a complete description of the decimal instructions.)

## ADD DECIMAL (AP)

Assume that the signed-packed-decimal number at storage locations 500-503 is to be added to the signed-packed-decimal number at locations 2000-2002. Also assume:

Register 12 contains 00 00 20 00.

Register 13 contains 00 00 05 00.

Storage locations 2000-2002 contain 38 46 0D (a negative number).

Storage locations 500-503 contain 01 12 34 5C (a positive number).

After the instruction:

#### Machine Format

| Op Code | L <sub>1</sub> | L <sub>2</sub> | B <sub>1</sub> | D <sub>1</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----------------|----------------|----------------|----------------|----------------|----------------|
| FA      | 2              | 3              | C              | 000            | D              | 000            |

#### Assembler Format

Op Code D<sub>1</sub>(L<sub>1</sub>,B<sub>1</sub>),D<sub>2</sub>(L<sub>2</sub>,B<sub>2</sub>)

AP 0(3,12),0(4,13)

is executed, the storage locations 2000-2002 contain 73 88 5C; condition code 2 is set to indicate that the result is greater than zero. Note that:

1. Because the two numbers had different signs, they were in effect subtracted.
2. Although the second operand is longer than the first operand, no overflow interruption occurs because the result can be entirely contained within the first operand.

## COMPARE DECIMAL (CP)

Assume that the signed-packed-decimal contents of storage locations 700-703 are to be algebraically compared with the signed-packed-decimal contents of locations 500-502. Also assume:

Register 12 contains 00 00 06 00.

Register 13 contains 00 00 03 00.

Storage locations 700-703 contain 17 25 35 6D.

Storage locations 500-502 contain 72 14 2D.

After the instruction:

#### Machine Format

| Op Code | L <sub>1</sub> | L <sub>2</sub> | B <sub>1</sub> | D <sub>1</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----------------|----------------|----------------|----------------|----------------|----------------|
| F9      | 3              | 2              | C              | 100            | D              | 200            |

#### Assembler Format

Op Code D<sub>1</sub>(L<sub>1</sub>,B<sub>1</sub>),D<sub>2</sub>(L<sub>2</sub>,B<sub>2</sub>)

CP X'100'(4,12),X'200'(3,13)

is executed, condition code 1 is set, indicating that the first operand (the contents of locations 700-703) is less than the second.

## DIVIDE DECIMAL (DP)

Assume that the signed-packed-decimal number at storage locations 2000-2004 (the dividend) is to be divided by the signed-packed-decimal number at locations 3000-3001 (the divisor). Also assume:

Register 12 contains 00 00 20 00.

Register 13 contains 00 00 30 00.

Storage locations 2000-2004 contain 01 23 45 67 8C.

Storage locations 3000-3001 contain 32 1D.

After the instruction:

Machine Format

| Op Code | L <sub>1</sub> | L <sub>2</sub> | B <sub>1</sub> | D <sub>1</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----------------|----------------|----------------|----------------|----------------|----------------|
| FD      | 4              | 1              | C              | 000            | D              | 000            |

Assembler Format

Op Code D<sub>1</sub>(L<sub>1</sub>,B<sub>1</sub>),D<sub>2</sub>(L<sub>2</sub>,B<sub>2</sub>)

DP 0(5,12),0(2,13)

is executed, the dividend is entirely replaced by the signed quotient and remainder, as follows:

|                     |          |    |           |
|---------------------|----------|----|-----------|
|                     | 2000     |    | 2004      |
| Locations 2000-2004 | 38       | 46 | 0D 01 8C  |
|                     | quotient |    | remainder |

Notes:

1. Because the dividend and divisor have different signs, the quotient receives a negative sign.
2. The remainder receives the sign of the dividend and the length of the divisor.
3. If an attempt were made to divide the dividend by the one-byte field at location 3001, the quotient would be too long to fit within the four bytes allotted to it. A decimal-divide exception would exist, causing a program interruption.

## EDIT (ED)

Before data in the signed-packed-decimal or unsigned-packed-decimal format can be used in a

printed report, digits and signs must be converted to printable characters. Moreover, punctuation marks, such as commas and decimal points, may have to be inserted in appropriate places. The highly flexible EDIT instruction performs these functions in a single instruction execution.

This example shows step-by-step one way that the EDIT instruction can be used. The field to be edited (the source) is four bytes long; it is edited against a pattern 13 bytes long. The following symbols are used:

| Symbol             | Meaning              |
|--------------------|----------------------|
| b (Hexadecimal 40) | Blank character      |
| ( (Hexadecimal 21) | Significance starter |
| d (Hexadecimal 20) | Digit selector       |

Assume that register 12 contains:

00 00 10 00

and that the source and pattern fields are:

Source

1200 1203

|    |    |    |    |
|----|----|----|----|
| 02 | 57 | 42 | 6C |
|----|----|----|----|

↑  
+

Pattern

1000

100C

|    |    |    |    |    |    |    |    |    |    |    |    |    |
|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 40 | 20 | 20 | 6B | 20 | 21 | 20 | 4B | 20 | 20 | 40 | C3 | D9 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|

b d d , d ( d . d d b C R

Execution of the instruction:

Machine Format

| Op Code | L  | B <sub>1</sub> | D <sub>1</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----|----------------|----------------|----------------|----------------|
| DE      | 0C | C              | 000            | C              | 200            |

Assembler Format

Op Code D<sub>1</sub>(L,B<sub>1</sub>),D<sub>2</sub>(B<sub>2</sub>)

ED 0(13,12),X'200'(12)

alters the pattern field as follows:

## Pattern

|      |    |    |    |    |      |    |    |    |    |    |    |    |
|------|----|----|----|----|------|----|----|----|----|----|----|----|
| 1000 |    |    |    |    | 100C |    |    |    |    |    |    |    |
| 40   | 40 | 40 | 40 | 40 | 5B   | F0 | 4B | F2 | F6 | 40 | C3 | D9 |
| b    | b  | b  | b  | b  | \$   | 0  | .  | 2  | 6  | b  | C  | R  |

This pattern field prints as:

\$0.26 CR

Condition code 1 is set because the number is less than zero.

## MULTIPLY DECIMAL (MP)

Assume that the signed-packed-decimal number in storage locations 1202-1204 (the multiplicand) is to be multiplied by the signed-packed-decimal number in locations 500-501 (the multiplier).

|              |      |    |      |  |
|--------------|------|----|------|--|
|              | 1202 |    | 1204 |  |
| Multiplicand | 38   | 46 | 0D   |  |
|              | 500  |    | 501  |  |
| Multiplier   | 32   | 1D |      |  |

The multiplicand must first be extended to have at least two bytes of leftmost zeros, corresponding to the multiplier length, so as to avoid a data exception during the multiplication. ZERO AND ADD can be used to move the multiplicand into a longer field. Assume:

Register 4 contains 00 00 12 00.

Register 6 contains 00 00 05 00.

Then execution of the instruction:

ZAP X'100'(5,4),2(3,4)

sets up a new multiplicand in storage locations 1300-1304:

|                    |      |    |      |    |    |
|--------------------|------|----|------|----|----|
|                    | 1300 |    | 1304 |    |    |
| Multiplicand (new) | 00   | 00 | 38   | 46 | 0D |

Now, after the instruction:

## Machine Format

| Op Code | L <sub>1</sub> | L <sub>2</sub> | B <sub>1</sub> | D <sub>1</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----------------|----------------|----------------|----------------|----------------|----------------|
| FC      | 4              | 1              | 4              | 100            | 6              | 000            |

## Assembler Format

Op Code D<sub>1</sub>(L<sub>1</sub>,B<sub>1</sub>),D<sub>2</sub>(L<sub>2</sub>,B<sub>2</sub>)

MP X'100'(5,4),0(2,6)

is executed, storage locations 1300-1304 contain the product: 01 23 45 66 0C.

## SHIFT AND ROUND DECIMAL (SRP)

The SHIFT AND ROUND DECIMAL (SRP) instruction can be used for shifting decimal numbers in storage to the left or right. When a number is shifted right, rounding can also be done.

### Decimal Left Shift

In this example, the contents of storage location FIELD1 are shifted three places to the left, effectively multiplying the contents of FIELD1 by 1000. FIELD1 is six bytes long. The following instruction performs the operation:

## Machine Format

| Op Code | L <sub>1</sub> | I <sub>3</sub> | S <sub>1</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----------------|----------------|----------------|----------------|----------------|
| F0      | 5              | 0              | * * * *        | 0              | 003            |

## Assembler Format

Op Code S<sub>1</sub>(L<sub>1</sub>),S<sub>2</sub>,I<sub>3</sub>

SRP FIELD1(6),3,0

FIELD1 (before): 00 01 23 45 67 8C

FIELD1 (after): 12 34 56 78 00 0C

The second-operand address in this instruction specifies the shift amount (three places). The rounding digit, I<sub>3</sub>, is not used in a left shift, but it must be a valid decimal digit. After execution, condition code 2 is set to show that the result is greater than zero.

### Decimal Right Shift

In this example, the contents of storage location FIELD2 are shifted one place to the right, effectively

dividing the contents of FIELD2 by 10 and discarding the remainder. FIELD2 is five bytes in length. The following instruction performs this operation:

### Machine Format

### Assembler Format

```
Op Code  S1(L1),S2,I3
-----
SRP      FIELD2(5),64-1,0
```

FIELD 2 (before): 01 23 45 67 8C

FIELD 2 (after): 00 12 34 56 7C

In the SRP instruction, shifts to the right are specified in the second-operand address by negative shift values, which are represented as a six-bit value in two's complement form.

The six-bit two's complement of a number, n, can be specified as 64 - n. In this example, a right shift of one is represented as 64 - 1.

Condition code 2 is set.

### Decimal Right Shift and Round

In this example, the contents of storage location FIELD3 are shifted three places to the right and rounded, in effect dividing by 1000 and rounding up. FIELD3 is four bytes in length.

### Machine Format

### Assembler Format

```
Op Code  S1(L1),S2,I3
-----
SRP      FIELD3(4),64-3,5
```

FIELD 3 (before): 12 39 60 0D

FIELD 3 (after): 00 01 24 0D

The shift amount (three places) is specified in the D<sub>2</sub> field. The I<sub>3</sub> field specifies a rounding digit of 5. The rounding digit is added to the last digit shifted out (which is a 6), and the carry is propagated to the left. The sign is ignored during the addition.

Condition code 1 is set because the result is less than zero.

### Multiplying by a Variable Power of 10

Since the shift value specified by the SRP instruction specifies both the direction and amount of the shift, the operation is equivalent to multiplying the decimal first operand by 10 raised to the power specified by the shift value.

If the shift value is to be variable, it may be specified by the B<sub>2</sub> field instead of the displacement D<sub>2</sub> of the SRP instruction. The general register designated by B<sub>2</sub> should contain the shift value (power of 10) as a signed binary integer.

A fixed scale factor modifying the variable power of 10 may be specified by using both the B<sub>2</sub> field (variable part in a general register) and the D<sub>2</sub> field (fixed part in the displacement).

The SRP instruction uses only the rightmost six bits of the effective address D<sub>2</sub>(B<sub>2</sub>) and interprets them as a six-bit signed binary integer to control the left or right shift as in the preceding shift examples.

## ZERO AND ADD (ZAP)

Assume that the signed-packed-decimal number at storage locations 4500-4502 is to be moved to locations 4000-4004 with four leading zeros in the result field. Also assume:

Register 9 contains 00 00 40 00.

Storage locations 4000-4004 contain 12 34 56 78 90.

Storage locations 4500-4502 contain 38 46 0D.

After the instruction:

Machine Format

| Op Code | L <sub>1</sub> | L <sub>2</sub> | B <sub>1</sub> | D <sub>1</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----------------|----------------|----------------|----------------|----------------|----------------|
| F8      | 4              | 2              | 9              | 000            | 9              | 500            |

Assembler Format

Op Code D<sub>1</sub>(L<sub>1</sub>,B<sub>1</sub>),D<sub>2</sub>(L<sub>2</sub>,B<sub>2</sub>)

ZAP 0(5,9),X'500'(3,9)

is executed, the storage locations 4000-4004 contain 00 00 38 46 0D; condition code 1 is set to indicate a negative result without overflow.

Note that, because the first operand is not checked for valid sign and digit codes, it may contain any combination of hexadecimal digits before the operation.

## Hexadecimal-Floating-Point Instructions

(See Chapter 9, "Floating-Point Overview and Support Instructions" for a complete description of the hexadecimal-floating-point instructions.)

In this section, the abbreviations FPR0, FPR2, FPR4, and FPR6 stand for floating-point registers 0, 2, 4, and 6 respectively.

## ADD NORMALIZED (AD, ADR, AE, AER, AXR)

The ADD NORMALIZED instruction performs the addition of two HFP numbers and places the normal-

ized result in a floating-point register. Neither of the two numbers to be added must necessarily be in normalized form before addition occurs. For example, assume that:

FPR6 contains the unnormalized number C3 08 21 00 00 00 00 00 =  $-82.1_{16} = -130.06_{10}$  approximately.

Storage locations 2000-2007 contain the normalized number 41 12 34 56 00 00 00 00 =  $+1.23456_{16} = +1.14_{10}$  approximately.

Register 13 contains 00 00 20 00.

The instruction:

Machine Format

| Op Code | R <sub>1</sub> | X <sub>2</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----------------|----------------|----------------|----------------|
| 7A      | 6              | 0              | D              | 000            |

Assembler Format

Op Code R<sub>1</sub>,D<sub>2</sub>(X<sub>2</sub>,B<sub>2</sub>)

AE 6,0(0,13)

performs the short-precision addition of the two operands, as follows.

The characteristics of the two numbers (43 and 41) are compared. Since the number in storage has a characteristic that is smaller by 2, it is right-shifted two hexadecimal digit positions. One guard digit is retained on the right. The fractions of the two numbers are then added algebraically:

|                             | Fraction GD <sup>1</sup> |
|-----------------------------|--------------------------|
| FPR6                        | -43 08 21 00             |
| Shifted number from storage | +43 00 12 34 5           |
| Intermediate sum            | -43 08 0E CB B           |
| Left-shifted sum            | -42 80 EC BB             |

<sup>1</sup> Guard digit

Because the intermediate sum is unnormalized, it is left-shifted to form the normalized HFP number  $-80.ECBB_{16} = -128.92_{10}$  approximately. Combining the sign with the characteristic, the result is C2 80 EC BB, which replaces the left half of FPR6. The right half of FPR6 and the contents of storage locations 2000-2007 are unchanged. Condition code 1 is set to indicate a result less than zero.

If the long-precision instruction AD were used, the result in FPR6 would be C2 80 EC BA A0 00 00 00. Note that use of the long-precision instruction would avoid a loss of precision in this example.

## ADD UNNORMALIZED (AU, AUR, AW, AWR)

The ADD UNNORMALIZED instruction operates the same as the ADD NORMALIZED instruction, except that the final result is not normalized. For example, using the same operands as in the example for ADD NORMALIZED, when the short-precision instruction:

### Machine Format

| Op Code | R <sub>1</sub> | X <sub>2</sub> | B <sub>2</sub> | D <sub>2</sub> |
|---------|----------------|----------------|----------------|----------------|
| 7E      | 6              | 0              | D              | 000            |

### Assembler Format

Op Code R<sub>1</sub>,D<sub>2</sub>(X<sub>2</sub>,B<sub>2</sub>)

AU 6,0(0,13)

is executed, the two numbers are added as follows:

|                             | Fraction GD <sup>1</sup> |
|-----------------------------|--------------------------|
| FPR6                        | -43 08 21 00             |
| Shifted number from storage | +43 00 12 34 5           |
| Intermediate sum            | -43 08 0E CB B           |

<sup>1</sup> Guard digit

The guard digit participates in the addition but is discarded. The unnormalized sum replaces the left half of FPR6. Condition code 1 is set because the result is less than zero.

The truncated result in FPR6 (C3 08 0E CB 00 00 00 00) shows a loss of a significant digit when compared to the result of short-precision normalized addition.

## COMPARE (CD, CDR, CE, CER)

Assume that FPR4 contains 43 00 00 00 00 00 00 00 (zero), and FPR6 contains 35 12 34 56 78 9A BC DE (a positive number). The contents of the two registers are to be compared using a long-precision COMPARE instruction.

### Machine Format

| Op Code | R <sub>1</sub> | R <sub>2</sub> |
|---------|----------------|----------------|
| 29      | 4              | 6              |

### Assembler Format

Op Code R<sub>1</sub>,R<sub>2</sub>

CDR 4,6

The number with the smaller characteristic, which is in register FPR6, is right-shifted 43 - 35 hex (67 - 53 decimal) or 14 digit positions, so that the two characteristics agree. The shifted number is 43 00 00 00 00 00 00 00, with a guard digit of one. Therefore, when the two numbers are compared, condition code 1 is set, indicating that operand 1 in FPR4 is less than operand 2 in FPR6.

If the example is changed to a second operand with a characteristic of 34 instead of 35, so that FPR6 contains 34 12 34 56 78 9A BC DE, the operand is right-shifted 15 positions, leaving all fraction digits and the guard digit as zeros. Condition code 0 is set, indicating equality. This example shows that two HFP numbers with different characteristics or fractions may compare equal if the numbers are unnormalized or zero.

As another example of comparing unnormalized HFP numbers, 41 00 12 34 56 78 9A BC compares equal to all numbers of the form 3F 12 34 56 78 9A BC 0X (X represents any hexadecimal digit). When the COMPARE instruction is executed, the two rightmost digits are shifted right two places, the 0 becomes the guard digit, and the X does not participate in the comparison.

However, when two normalized HFP numbers are compared, the relationship between numbers that compare equal is unique: each digit in one number must be the same as the corresponding digit in the other number.

## DIVIDE (DD, DDR, DE, DER)

Assume that the first operand (the dividend) is in FPR2 and the second operand (the divisor) in FPR0. If the operands are in the short-precision format, the resulting quotient is returned to FPR2 by the instruction:

## Machine Format

| Op Code | R <sub>1</sub> | R <sub>2</sub> |
|---------|----------------|----------------|
| 3D      | 2              | 0              |

## Assembler Format

| Op Code | R <sub>1</sub> ,R <sub>2</sub> |
|---------|--------------------------------|
| DER     | 2,0                            |

Several examples of short-precision HFP division, with the dividend in FPR2 and the divisor in FPR0, are shown below. For case A, the result, which replaces the dividend, is obtained in the following steps.

|         |          |
|---------|----------|
|         | 7.2522F  |
| .123400 | 821000   |
|         | 7F6C00   |
|         | 2A400 0  |
|         | 24680 0  |
|         | 5D80 00  |
|         | 5B04 00  |
|         | 27C 000  |
|         | 246 800  |
|         | 35 8000  |
|         | 24 6800  |
|         | 11 18000 |
|         | 11 10C00 |
|         | 7400     |

| Case | FPR2 Before<br>(Dividend) | FPR0 (Divisor) | FPR2 After<br>(Quotient) |
|------|---------------------------|----------------|--------------------------|
| A    | -43 082100                | +43 001234     | -42 72522F               |
| B    | +42 101010                | +45 111111     | +3D F0F0F0               |
| C    | +48 30000F                | +41 400000     | +47 C0003C               |
| D    | +48 30000F                | +41 200000     | +48 180007               |
| E    | +48 180007                | +41 200000     | +47 C00038               |

Case C shows a number being divided by 4.0. Case D divides the same number by 2.0, and case E divides the result of case D again by 2.0. The results of cases C and E differ in the rightmost hexadecimal digit position, which illustrates an effect of result truncation.

## HALVE (HDR, HER)

HALVE produces the same result as HFP DIVIDE with a divisor of 2.0. Assume FPR2 contains the long-precision number +48 30 00 00 00 00 0F. The following HALVE instruction produces the result +48 18 00 00 00 00 07 in FPR2:

## Machine Format

| Op Code | R <sub>1</sub> | R <sub>2</sub> |
|---------|----------------|----------------|
| 24      | 2              | 2              |

## Assembler Format

| Op Code | R <sub>1</sub> ,R <sub>2</sub> |
|---------|--------------------------------|
| HDR     | 2,2                            |

## MULTIPLY (MD, MDR, MDE, MDER, MXD, MXDR, MXR)

For this example, the following long-precision operands are in FPR0 and FPR2:

FPR0: -33 606060 60606060  
FPR2: -5A 200000 20000020

A long-precision product is generated by the instruction:

## Machine Format

| Op Code | R <sub>1</sub> | R <sub>2</sub> |
|---------|----------------|----------------|
| 2C      | 0              | 2              |

## Assembler Format

| Op Code | R <sub>1</sub> ,R <sub>2</sub> |
|---------|--------------------------------|
| MDR     | 0,2                            |

If the operands were not already normalized, the instruction would first normalize them. It then generates an intermediate result consisting of the full 28-digit hexadecimal product fraction obtained by multiplying the 14-digit hexadecimal operand fractions, together with the appropriate sign and a characteristic that is the sum of the operand characteristics less 64 (40 hex):

The fraction multiplication is performed as follows:

```

      .60606060606060
      .20000020000020
      -----
      C0C0C0C0C0C0C0
    C0C0C0C0C0C0C0
      C0C0C0C0C0C0C0
      -----
    .0C0C0C181818241818180C0C0C0
  
```

Attaching the sign and characteristic to the fraction gives:

```
+4D 0C0C0C 18181824 1818180C 0C0C00
```

Because this intermediate product has a leading zero, it is then normalized. The truncated final result placed in FPR0 is:

```
+4C C0C0C1 81818241
```

## Hexadecimal-Floating-Point-Number Conversion

The following examples illustrate one method of converting between binary fixed-point numbers (32-bit signed binary integers) and normalized HFP numbers. Conversion must provide for the different representations used with negative numbers: the two's-complement form for signed binary integers, and the signed-absolute-value form for the fractions of HFP numbers.

### Fixed Point to Hexadecimal Floating Point

The method used here inverts the leftmost bit of the 32-bit signed binary integer, which is equivalent to adding  $2^{31}$  to the number and considering the result to be positive. This changes the number from a signed integer in the range  $2^{31} - 1$  through  $-2^{31}$  to an unsigned integer in the range  $2^{32} - 1$  through 0. After conversion to the long HFP format, the value  $2^{31}$  is subtracted again.

Assume that general register 9 (GR9) contains the integer -59 in two's-complement form:

```
GR9:    FF FF FF C5
```

Further, assume two eight-byte fields in storage: TEMP, for use as temporary storage, and TWO31,

which contains the floating-point constant  $2^{31}$  in the following format:

```
TWO31:  4E 00 00 00 80 00 00 00
```

This is an unnormalized long HFP number with the characteristic 4E, which corresponds to a radix point (hexadecimal point) to the right of the number.

The following instruction sequence performs the conversion:

|     |               | <b>Result</b>                |
|-----|---------------|------------------------------|
| X   | 9,TWO31+4     | GR9:<br>7FFF FFC5            |
| ST  | 9,TEMP+4      | TEMP:<br>xxxx xxxx 7FFF FFC5 |
| MVC | TEMP(4),TWO31 | TEMP:<br>4E00 0000 7FFF FFC5 |
| LD  | 2,TEMP        | FPR2:<br>4E00 0000 7FFF FFC5 |
| SD  | 2,TWO31       | FPR2:<br>C23B 0000 0000 0000 |

The EXCLUSIVE OR (X) instruction inverts the leftmost bit in general register 9, using the right half of the constant as the source for a leftmost one bit. The next two instructions assemble the modified number in an unnormalized long HFP format, using the left half of the constant as the plus sign, the characteristic, and the leading zeros of the fraction. LOAD (LD) places the number unchanged in floating-point register 2. The SUBTRACT NORMALIZED (SD) instruction performs the final two steps by subtracting  $2^{31}$  in HFP form and normalizing the result.

### Hexadecimal Floating Point to Fixed Point

The procedure described here consists basically in reversing the steps of the previous procedure. Two additional considerations must be taken into account. First: the HFP number may not be an exact integer. Truncating the excess hexadecimal digits on the right requires shifting the number one digit position farther to the right than desired for the final result, so that the units digit occupies the position of the guard digit. Second: the HFP number may have to be tested as to whether it is outside the range of numbers representable as a 32-bit signed binary integer.

Assume that floating-point register 6 contains the number  $59.25_{10} = 3B.4_{16}$  in normalized form:

```
FPR6:    42 3B 40 00 00 00 00 00
```

Further, assume three eight-byte fields in storage: TEMP, for use as temporary storage, and the constants  $2^{32}$  (TWO32) and  $2^{31}$  (TWO31R) in the following formats:

```
TWO32:    4E 00 00 01 00 00 00 00
TWO31R:   4F 00 00 00 08 00 00 00
```

The constant TWO31R is shifted right one more position than the constant TWO31 of the previous example, so as to force the units digit into the guard-digit position.

The following instruction sequence performs the integer truncation, range tests, and conversion to a signed binary integer in general register 8 (GR8):

|     |              | <b>Result</b>                                                         |
|-----|--------------|-----------------------------------------------------------------------|
| SD  | 6,TWO31R     | FPR6:<br>C87F FFFF C500 0000                                          |
| BC  | 11,OVERFLOW  | Branch to overflow routine if result is greater than or equal to zero |
| AW  | 6,TWO32      | FPR6:<br>4E00 0000 8000 003B                                          |
| BC  | 4,OVERFLOW   | Branch to overflow routine if result is less than zero                |
| STD | 6,TEMP       | TEMP:<br>4E00 0000 8000 003B                                          |
| XI  | TEMP+4,X'80' | TEMP:<br>4E00 0000 0000 003B                                          |
| L   | 8,TEMP+4     | GR8:<br>0000 003B                                                     |

The SUBTRACT NORMALIZED (SD) instruction shifts the fraction of the number to the right until it lines up with TWO31R, which causes the fraction digit 4 to fall to the right of the guard digit and be lost; the result of subtracting  $2^{31}$  from the remaining digits is renormalized. The result should be less than zero; if not, the original number was too large in the positive direction. The first BRANCH ON CONDITION (BC) performs this test.

The ADD UNNORMALIZED (AW) instruction adds  $2^{32}$ :  $2^{31}$  to correct for the previous subtraction and another  $2^{31}$  to change to an all-positive range. The second BC tests for a result less than zero, showing that the original number was too large in the negative direction. The unnormalized result is placed in temporary storage by the STORE (STD) instruction. There the leftmost bit of the binary integer is inverted by the EXCLUSIVE OR (XI) instruction to subtract  $2^{31}$

and thus convert the unsigned number to the signed format. The final result is loaded into GR8.

## Multiprogramming and Multiprocessing Examples

When two or more programs sharing common storage locations are being executed concurrently in a multiprogramming or multiprocessing environment, one program may, for example, set a flag bit in the common-storage area for testing by another program. It should be noted that the instructions AND (NI, NIY, or NC), EXCLUSIVE OR (XI, XIY, or XC), and OR (OI, OIY, or OC) could be used to set flag bits in a multiprogramming environment; but when the interlocked-access facility 2 is not installed, the same instructions may cause program logic errors in a multiprocessing configuration where two or more CPUs can fetch, modify, and store data in the same storage locations simultaneously.

### Example of a Program Failure Using OR Immediate

The following example assumes that the interlocked-access facility 2 is not installed.

Assume that two independent programs try to set different bits to one in a common byte in storage. The following example shows how the use of the instruction OR immediate (OI) can fail to accomplish this, if the programs are executed simultaneously on two different CPUs. One of the possible error situations is depicted.

| Execution of instruction<br>OI FLAGS,X'01' on<br>CPU A   | FLAGS | Execution of instruction<br>OI FLAGS,X'80' on<br>CPU B |
|----------------------------------------------------------|-------|--------------------------------------------------------|
| Fetch FLAGS X'00'                                        | X'00' | Fetch FLAGS X'00'                                      |
| OR X'01' into X'00'                                      | X'00' | OR X'80' into X'00'                                    |
| Store X'01' into FLAGS                                   | X'80' | Store X'80' into FLAGS                                 |
| FLAGS should have value of X'81' following both updates. |       |                                                        |

The problem shown here is that the value stored by the OI instruction executed on CPU A overlays the value that was stored by CPU B. The X'80' flag bit

was erroneously turned off, and the data is now invalid.

The COMPARE AND SWAP instruction has been provided to overcome this and similar problems.

When the interlocked-access facility 2 is installed, the update performed by OR (OI) instruction is an interlocked-update reference, and the problem illustrated here does not occur.

## Conditional Swapping Instructions (CS, CDS)

The COMPARE AND SWAP (CS) and COMPARE DOUBLE AND SWAP (CDS) instructions can be used in multiprogramming or multiprocessing environments to serialize access to counters, flags, control words, and other common storage areas.

The following examples of the use of the COMPARE AND SWAP and COMPARE DOUBLE AND SWAP instructions illustrate the applications for which the instructions are intended. It is important to note that these are examples of functions that can be performed by programs while the CPU is enabled for interruption (multiprogramming) or by programs that are being executed in a multiprocessing configuration. That is, the routine allows a program to modify the contents of a storage location while the CPU is enabled, even though the routine may be interrupted by another program on the same CPU that will update the location, and even though the possibility exists that another CPU may simultaneously update the same location.

The COMPARE AND SWAP instruction first checks the value of a storage location and then modifies it only if the value is what the program expects; normally this would be a previously fetched value. If the value in storage is not what the program expects, then the location is not modified; instead, the current value of the location is loaded into a general register, in preparation for the program to loop back and try again. During the execution of COMPARE AND SWAP, no other CPU can perform a store access or interlocked-update access at the specified location.

To ensure successful updating of a common storage field by two or more CPUs, all updates must be done by means of an interlocked-update reference. See the programming notes of COMPARE AND SWAP for

an example of how COMPARE AND SWAP can be unsuccessful due to an OR IMMEDIATE instruction executed by another CPU.

### Setting a Single Bit

The following instruction sequence shows how the COMPARE AND SWAP instruction can be used to set a single bit in storage to one. Assume that the first byte of a word in storage called "WORD" contains eight flag bits.

```

LA  6,X'80'  Put bit to be 0Red into GR6
SLL 6,24     Shift left 24 places to
              align the byte to be 0Red
              with the location of the
              flag bits within WORD
L   7,WORD   Fetch current flag values
RETRY LR 8,7  Load flags into GR8
OR  8,6      Set bit to one
CS  7,8,WORD Store new flags if current
              flags unchanged, or re-
              fetch current flag values
              if changed
BC  4,RETRY  If new flags are not stored,
              try again

```

The format of the COMPARE AND SWAP instruction is:

#### Machine Format

| Op Code | R <sub>1</sub> | R <sub>3</sub> | S <sub>2</sub> |
|---------|----------------|----------------|----------------|
| BA      | 7              | 8              | * * * *        |

#### Assembler Format

| Op Code | R <sub>1</sub> , R <sub>3</sub> , S <sub>2</sub> |
|---------|--------------------------------------------------|
| CS      | 7,8,WORD                                         |

The COMPARE AND SWAP instruction compares the first operand (general register 7 containing the current flag values) to the second operand in storage (WORD) while no CPU other than the one executing the COMPARE AND SWAP instruction is permitted to perform a store access or interlocked-update access at the specified storage location.

If the comparison is successful, indicating that the flag bits have not been changed since they were fetched, the modified copy in general register 8 is stored into WORD. If the flags have been changed, the compare will not be successful, and their new values are loaded into general register 7.

The conditional branch (BC) instruction tests the condition code and reexecutes the flag-modifying instructions if the COMPARE AND SWAP instruction indicated an unsuccessful comparison (condition code 1). When the COMPARE AND SWAP instruction is successful (condition code 0), the flags contain valid data, and the program exits from the loop.

The branch to RETRY will be taken only if some other program modifies the contents of WORD. This type of a loop differs from the typical “bit-spin” loop. In a bit-spin loop, the program continues to loop until the bit changes. In this example, the program continues to loop only if the value does change during each iteration. If a number of CPUs simultaneously attempt to modify a single location by using the sample instruction sequence, one CPU will fall through on the first try, another will loop once, and so on until all CPUs have succeeded.

## Updating Counters

In this example, a 32-bit counter is updated by a program using the COMPARE AND SWAP instruction to ensure that the counter will be correctly updated. The original value of the counter is obtained by loading the word containing the counter into general register 7. This value is moved into general register 8 to provide a modifiable copy, and general register 6 (containing an increment to the counter) is added to the modifiable copy to provide the updated counter value. The COMPARE AND SWAP instruction is used to ensure valid storing of the counter.

The program updating the counter checks the result by examining the condition code. The condition code 0 indicates a successful update, and the program can proceed. If the counter had been changed between the time that the program loaded its original value and the time that it executed the COMPARE AND SWAP instruction, the execution would have loaded the new counter value into general register 7 and set the condition code to 1, indicating an unsuccessful update. The program must then repeat the update sequence until the execution of the COMPARE AND SWAP instruction results in a successful update.

The following instruction sequence performs the above procedure:

```
LA 6,1      Put increment (1) into GR6
L  7,CNTR   Put original counter value
              into GR7
```

```
LOOP LR 8,7      Set up copy in GR8 to modify
AR 8,6      Increment copy
CS 7,8,CNTR   Update counter in storage
BC 4,LOOP    If original value had
              changed, update new value
```

The following shows two CPUs, A and B, executing this instruction sequence simultaneously: both CPUs attempt to add one to CNTR.

| CPU A |     |      | CPU B |     | Comments                                               |
|-------|-----|------|-------|-----|--------------------------------------------------------|
| GR7   | GR8 | CNTR | GR7   | GR8 |                                                        |
|       |     | 16   |       |     |                                                        |
| 16    | 16  |      |       |     | CPU A loads GR7 and GR8 from CNTR                      |
|       |     |      | 16    | 16  | CPU B loads GR7 and GR8 from CNTR                      |
|       |     |      |       | 17  | CPU B adds one to GR8                                  |
|       | 17  |      |       |     | CPU A adds one to GR8                                  |
|       |     | 17   |       |     | CPU A executes CS; successful match, store             |
|       |     |      | 17    |     | CPU B executes CS; no match, GR7 changed to CNTR value |
|       |     |      |       | 18  | CPU B loads GR8 from GR7, adds one to GR8              |
|       |     | 18   |       |     | CPU B executes CS; successful match, store             |

## Bypassing Post and Wait

See the *MVS Programming: Authorized Assembler Services Guide* (SA22-7608) for details on bypassing the z/OS WAIT and POST routines.

## Lock/Unlock

When a common storage area larger than a double-word is to be updated, it is usually necessary to provide special interlocks to ensure that a single program at a time updates the common area. Such an area is called a serially reusable resource (SRR).

In general, updating a list, or even scanning a list, cannot be safely accomplished without first “freezing” the list. However, the COMPARE AND SWAP and COMPARE DOUBLE AND SWAP instructions can be used in certain restricted situations to perform queuing and list manipulation. Of prime importance is the capability to perform the lock/unlock functions and to provide sufficient queuing to resolve contentions, either in a LIFO or FIFO manner. The lock/unlock

functions can then be used as the interlock mechanism for updating an SRR of any complexity.

The lock/unlock functions are based on the use of a “header” associated with the SRR. The header is the common starting point for determining the states of the SRR, either free or in use, and also is used for queuing requests when contentions occur. Contentions are resolved using WAIT and POST. The general programming technique requires that the program that encounters a “locked” SRR must “leave a mark on the wall” indicating the address of an ECB on which it will WAIT. The “unlocking” program sees the mark and posts the ECB, thus permitting the waiting program to continue. In the two examples given, all programs using a particular SRR must use either the LIFO queuing scheme or the FIFO scheme; the two cannot be mixed. When more complex queuing is required, it is suggested that the queue for the SRR be locked using one of the two methods shown.

### Lock/Unlock with LIFO Queuing for Contentions

The header consists of a word, that is, a four-byte field aligned on a word boundary. The word can contain zero, a positive value, or a negative value.

- A zero value indicates that the serially reusable resource (SRR) is free.
- A negative value indicates that the SRR is in use but no additional programs are waiting for the SRR.
- A positive value indicates that the SRR is in use and that one or more additional programs are waiting for the SRR. Each waiting program is identified by an element in a chained list. The positive value in the header is the address of the element most recently added to the list.

Each element consists of two words. The first word is used as an ECB; the second word is used as a pointer to the next element in the list. A negative value in a pointer indicates that the element is the last element in the list. The element is required only if the program finds the SRR locked and desires to be placed in the list.

The following chart describes the action taken for LIFO LOCK and LIFO UNLOCK routines. The rou-

tines following the chart allow enabled code to perform the actions described in the chart.

| Function                                             | Action                                                        |                                                                                                                                              |                                                                  |
|------------------------------------------------------|---------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------|
|                                                      | Header Contains Zero                                          | Header Contains Positive Value                                                                                                               | Header Contains Negative Value                                   |
| LIFO LOCK<br>(the incoming element is at location A) | SRR is free. Set the header to a negative value. Use the SRR. | SRR is in use. Store the contents of the header into location A+4. Store address A into the header. WAIT; the ECB is at location A.          |                                                                  |
| LIFO UNLOCK                                          | Error                                                         | Some program is waiting for the SRR. Move the pointer from the “last in” element into the header. POST; the ECB is in the “last in” element. | The list is empty. Store zeros into the header. The SRR is free. |

#### LIFO LOCK Routine:

Initial Conditions:

- GR1 contains the address of the incoming element.
- GR2 contains the address of the header.

```

LLOCK  SR    3,3      GR3 = 0
        ST    3,0(1)   Initialize the ECB
        LNR   0,1      GR0 = a negative value
TRYAGN CS   3,0,0(2)  Set the header to a
                        negative value if the
                        header contains zeros
        BC    8,USE    Did the header contain
                        zeros?
        ST    3,4(1)   No, store the value of
                        the header into the
                        pointer in the in-
                        coming element
        CS    3,1,0(2) Store the address of
                        the incoming element
                        into the header
        LA    3,0(0)   GR3 = 0
        BC    7,TRYAGN Did the header get up-
                        dated?
        WAIT  ECB=(1)  Yes, wait for the re-
                        source; the ECB is in
                        the incoming element
USE     [Any instruction]
```

### **LIFO UNLOCK Routine:**

Initial Conditions:

- GR2 contains the address of the header.

```
LUNLK L    1,0(2)    GR1 = the contents of
                     the header
A    LTR  1,1        Does the header contain
    BC   4,B         a negative value?
    L    0,4(1)      No, load the pointer
    CS   1,0,0(2)    from the 'last in'
                     element and store it in
                     the header
    BC   7,A         Did the header get
                     updated?
    POST (1)         Yes, post the 'last in'
                     element
    BC   15,EXIT      Continue
B    SR    0,0        The header contains a
    CS   1,0,0(2)    negative value; free
    BC   7,A         the header and continue
EXIT [Any instruction]
```

Note that the LOAD instruction L 1,0(2) at location LUNLK would have to be CS 1,1,0(2) if it were not for the rule concerning storage-operand consistency. This rule requires the LOAD instruction to fetch a four-byte operand aligned on a word boundary such that, if another CPU changes the word being fetched by an operation which is also at least word-consistent, either the entire new or the entire old value of the word is obtained, and not a combination of the two. (See "Storage-Operand Consistency" on page 5-123.)

### **Lock/Unlock with FIFO Queuing for Contentions**

The header always contains the address of the most recently entered element. The header is originally initialized to contain the address of a posted ECB. Each program using the serially reusable resource (SRR) must provide an element regardless of whether contention occurs. Each program then enters the address of the element which it has provided into the header, while simultaneously it removes the address previously contained in the header. Thus, associated with any particular program attempting to use the SRR are two elements, called the "entered element" and the "removed element". The "entered element" of one program becomes the "removed element" for the immediately following program. Each program then waits on the removed element, uses the SRR, and then posts the entered element.

When no contention occurs, that is, when the second program does not attempt to use the SRR until after the first program is finished, then the POST of the first program occurs before the WAIT of the second program. In this case, the bypass-post and bypass-wait routines described in the preceding section are applicable. For simplicity, these two routines are shown only by name rather than as individual instructions.

In the example, the element need be only a single word, that is, an ECB. However, in actual practice, the element could be made larger to include a pointer to the previous element, along with a program identification. Such information would be useful in an error situation to permit starting with the header and chaining through the list of elements to find the program currently holding the SRR.

It should be noted that the element provided by the program remains pointed to by the header until the next program attempts to lock. Thus, in general, the entered element cannot be reused by the program. However, the removed element is available, so each program gives up one element and gains a new one. It is expected that the element removed by a particular program during one use of the SRR would then be used by that program as the entry element for the next request to the SRR.

It should be noted that, since the elements are exchanged from one program to the next, the elements cannot be allocated from storage that would be freed and reused when the program ends. It is expected that a program would obtain its first element and release its last element by means of the routines described in "Free-Pool Manipulation".

The following chart describes the action taken for FIFO LOCK and FIFO UNLOCK.

| Function                                             | Action                                                                                                            |
|------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| FIFO LOCK<br>(the incoming element is at location A) | Store address A into the header.<br>WAIT; the ECB is at the location addressed by the old contents of the header. |
| FIFO UNLOCK                                          | POST; the ECB is at location A.                                                                                   |

The following routines allow enabled code to perform the actions described in the previous chart.

### **FIFO Lock Routine:**

Initial conditions:

- GR3 contains the address of the header.
- GR4 contains the address, A, of the element currently owned by this program. This element becomes the entered element.

```

FLOCK  LR   2,4      GR2 now contains
                        address of element to
                        be entered
        SR   1,1      GR1 = 0
        ST   1,0(2)   Initialize the ECB
        L    1,0(3)   GR1 = contents of the
                        header
TRYAGN CS   1,2,0(3) Enter address A into
                        header while remember-
        BC   7,TRYAGN ing old contents of
                        header into GR1; GR1
                        now contains address
                        of removed element
        LR   4,1      Removed element becomes
                        new currently owned
                        element
        HSWAIT        Perform bypass-wait
                        routine; if ECB
                        already posted, con-
                        tinue; if not, wait;
                        GR1 contains the
                        address of the ECB
USE     [Any instruction]

```

#### ***FIFO Unlock Routine:***

Initial conditions:

- GR2 contains the address of the removed element, obtained during the FLOCK routine.
- GR5 contains 40 00 00 00<sub>16</sub>

```

FUNLK  LR   1,2      Place address of entered
                        element in GR1; GR1 = ad-
                        dress of ECB to be posted
        SR   0,0      GR0 = 0; GR0 has a post code
                        of zero
        OR   0,5      Set bit 1 of GR0 to one
        HSPOST        Perform bypass-post routine;
                        if ECB has not been waited
                        on, then mark posted and
                        continue; if it has been
                        waited on, then post
CONTINUE [Any instruction]

```

## **Free-Pool Manipulation**

It is anticipated that a program will need to add and delete items from a free list without using the lock/unlock routines. This is especially likely since the lock/unlock routines require storage elements for queuing and may require working storage. The lock/unlock routines discussed previously allow simultaneous lock routines but permit only one unlock routine at a time. In such a situation, multiple additions and a single deletion to the list may all occur simultaneously, but multiple deletions cannot occur at the same time. In the case of a chain of pointers containing free storage buffers, multiple deletions along with additions can occur simultaneously. In this case, the removal cannot be done using the COMPARE AND SWAP instruction without a certain degree of exposure.

Consider a chained list of the type used in the example in section “Lock/Unlock with LIFO Queuing for Contentions” on page A-48. Assume that the first two elements are at locations A and B, respectively. If one program attempted to remove the first element and was interrupted between the fourth and fifth instructions of the LUNLK routine, the list could be changed so that elements A and C are the first two elements when the interrupted program resumes execution. The COMPARE AND SWAP instruction would then succeed in storing the value B into the header, thereby destroying the list.

The probability of the occurrence of such list destruction can be reduced to *near* zero by appending to the header a counter that indicates the number of times elements have been added to the list. The use of a 32-bit counter guarantees that the list will not be destroyed unless the following events occur, in the exact sequence:

1. An unlock routine is interrupted between the fetch of the pointer from the first element and the update of the header.
2. The list is manipulated, including the deletion of the element referenced in 1, and exactly  $2^{32}$  (or an integer multiple of  $2^{32}$ ) additions to the list are performed. Note that this takes on the order of days to perform in any practical situation.
3. The element referenced in 1 is added to the list.
4. The unlock routine interrupted in 1 resumes execution.

The following routines use such a counter in order to allow multiple, simultaneous additions and removals at the head of a chain of pointers.

The list consists of a doubleword header and a chain of elements. The first word of the header contains a pointer to the first element in the list. The second word of the header contains a 32-bit counter indicating the number of additions that have been made to the list. Each element contains a pointer to the next element in the list. A zero value indicates the end of the list.

The following chart describes the free-pool-list manipulation.

| Function                                            | Action                                                                                                                                                     |                                                                                             |
|-----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------|
|                                                     | Header = 0, Count                                                                                                                                          | Header = A, Count                                                                           |
| ADD TO LIST (the incoming element is at location A) | Store the first word of the header into location A. Store the address A into the first word of the header. Decrement the second word of the header by one. |                                                                                             |
| DELETE FROM LIST                                    | The list is empty.                                                                                                                                         | Set the first word of the header to the value of the contents of location A. Use element A. |

The following routines allow enabled code to perform the free-pool-list manipulation described in the above chart.

#### ***ADD TO FREE LIST Routine:***

Initial Conditions:

- GR2 contains the address of the element to be added.
- GR4 contains the address of the header.

```

ADDQ  LM    0,1,0(4)  GR0,GR1 = contents of
                        the header
TRYAGN ST    0,4(2)   Point the new element to
                        the top of the list
      LR     3,1      Move the count to GR3
      AHI    3,1      Increment the count
      CDS    0,2,0(4) Update the header
      BC     7,TRYAGN

```

#### ***DELETE FROM FREE LIST Routine:***

Initial conditions:

- GR4 contains the address of the header.

```

DELETQ LM    2,3,0(4)  GR2,GR3 = contents
                        of the header
TRYAGN LTR    2,2      Is the list empty?
      BC     8,EMPTY   Yes, get help
      L      0,4(2)    No, GR0 = the pointer
                        from the first
                        element
      LR     1,3      Move the count to GR1
      CDS    2,0,0(4)  Update the header
      BC     7,TRYAGN
USE     [Any instruction] The address of the re-
                        moved element is in
                        GR2

```

#### **Notes:**

1. The LM (LOAD MULTIPLE) instructions at locations ADDQ and DELETQ would have to be CDS (COMPARE DOUBLE AND SWAP) instructions if it were not for the rule concerning storage-operand consistency. This rule requires the LOAD MULTIPLE instructions to fetch an eight-byte operand aligned on a doubleword boundary such that, if another CPU changes the doubleword being fetched by an operation which is also at least doubleword-consistent, either the entire new or the entire old value of the doubleword is obtained, and not a combination of the two. (See "Storage-Operand Consistency" on page 5-123.)
2. The add-to-free-list and delete-from-free-list examples shown above assume that the pointer to the next element in the list is in the second word of the element, as described "Lock/Unlock with LIFO Queuing for Contentions" on page A-48.

## **PERFORM LOCKED OPERATION (PLO)**

The PERFORM LOCKED OPERATION instruction can be used in a multiprogramming or multiprocessing environment to perform compare, load, compare-and-swap, and store operations on two or more discontinuous locations that can be words or doublewords. The operations are performed as an atomic set of operations under the control of a lock that is held only for the duration of the execution of a single PERFORM LOCKED OPERATION instruction, as opposed to across the execution of multiple instructions. Since lock contention is resolved by the CPU and is very brief, the program need not include a method for dealing with the case when the lock to be

used is held by a program being executed by another CPU. Also, there need be no concern that the program may be interrupted while it holds a lock, since PERFORM LOCKED OPERATION will complete its operation and release its lock before an interruption can occur.

PERFORM LOCKED OPERATION can be thought of as performing concurrent interlocked updates of multiple operands. However, the instruction does not actually perform any interlocked update, and a serially reusable resource cannot be updated predictably through the use of both PERFORM LOCKED OPERATION and conditional-swapping instructions (CS and CDS).

Following is an example of how PERFORM LOCKED OPERATION can be used to add an element at the beginning of a queue.

Assume the following variables associated with the queue: S, which is a sequence number that is incremented anytime the queue is changed; H (for head), which is the address of the first element on the queue; and C, which is a count of the number of elements on the queue. Assume a queue element contains a variable, F (for forward), which is the address of the next element on the queue. If a new element, N, is to be enqueued at the head of the queue, that can be done by setting F in N to H and then performing the following atomic set of operations:

S+1 → S  
A(N) → H  
C+1 → C

where A(N) is the address of N.

The enqueueing of N can be done by means of the following steps:

1. Obtain consistent values of S, H, and C, meaning obtain S and obtain the H and C that are consistent with that value of S.
2. Store H in N.F.
3. By means of PLO.csdst (PERFORM LOCKED OPERATION performing compare and swap and double store), with S as the swap variable and H and C as the store variables, add one to S, set H to A(N), and add one to C, provided that S still has the value obtained in step 1. If S has already been changed, go back to step 1.

Consistent values of S, H, and C cannot necessarily be obtained simply by using three LOAD instructions because a PERFORM LOCKED OPERATION instruction being executed by another CPU may have completed an update of S but not yet of H or C. In this case, the three LOAD instructions will obtain the new S but the old H or C. However, as will be described, it may be possible to use three LOAD instructions.

If S is obtained while holding the lock, meaning by means of PERFORM LOCKED OPERATION, then H and C can be obtained by LOAD instructions since no other CPU can subsequently change H or C without changing S, as observed when the lock is held.

The parameter list used by the PLO.csdst is as follows, assuming the access-register mode is not used:

|     |      |
|-----|------|
| 0   |      |
| 8   |      |
| :   |      |
| 48  |      |
| 56  | A(N) |
| 64  |      |
| 72  | A(H) |
| 80  |      |
| 88  | C+1  |
| 96  |      |
| 104 | A(C) |

The program is as follows:

|       |           |                                       |
|-------|-----------|---------------------------------------|
| LA    | RT,H      | Initialize addresses in PL (T = temp) |
| ST    | RT,PL+76  | Op4 address (address of H)            |
| LA    | RT,C      |                                       |
| ST    | RT,PL+108 | Op6 address (address of C)            |
| LA    | RN,N      | Address of N                          |
| ST    | RN,PL+60  | Initialize op3 in PL (address of N)   |
| LA    | R1,S      | PLT address = address of S            |
| ----- |           |                                       |
| SR    | RS,RS     | Dummy S. CC1 will probably be set     |
| SR    | R0,R0     | Function code 0 (compare and load)    |

|       |     |               |                                    |
|-------|-----|---------------|------------------------------------|
|       | PLO | RS,S,RS,S     | Obtain S while holding lock        |
| ----- |     |               |                                    |
|       | LA  | R0,16         | Function code 16 (csdst)           |
| LOOP  | L   | RT,H          | Consistent H                       |
|       | ST  | RT,OFSTF(,RN) | OFSTF = offset of F in N           |
|       | L   | RT,C          | Consistent C                       |
|       | LA  | RT,1(,RT)     | C+1                                |
|       | ST  | RT,PL+92      | Initialize op5 in PL (C+1)         |
|       | LA  | RSP,1(,RS)    | RS/RSP = even-odd pair. S+1 in RSP |
|       | PLO | RS,S,0,PL     |                                    |
|       | BNZ | LOOP          | Br if S changed (if CC not 0)      |

Note the following about the first PERFORM LOCKED OPERATION instruction (PLO.cl). If S is not zero (which is probably true), S (the second operand, op2) is loaded into RS (the first-operand comparison value, op1c). If S is zero, S (the fourth operand, op4) is loaded into RS (the third operand, op3). Either of these loads occurs while the lock is held. It is unnecessary to test the condition code to determine which load occurred.

The above program may be a simplification. If the queue has associated with it a variable, T (for tail), that is the address of the last element on the queue, and the queue is currently empty, T also must be set when N is added to the queue. This would require a different program using a compare-and-swap-and-triple-store operation.

If the queue is added to, deleted from, and rearranged by means of PERFORM LOCKED OPERATION instructions in which the sequence number, S, is always the second operand, then, since the definition of PERFORM LOCKED OPERATION specifies that the second operand is always stored last, the first PERFORM LOCKED OPERATION instruction in the above program can be replaced by a LOAD instruction. The three instructions within the dashed lines would be replaced by L RS,S.

## Sorting Instructions

### Tree Format

Two instructions, COMPARE AND FORM CODE-WORD and UPDATE TREE, refer to a tree — a data structure with a specific format. A tree consists of some number (always odd) of consecutively numbered nodes. Node 1 is the root of the tree. Every node except the root has one parent node in the same tree. Every parent node has two son nodes. Every even-numbered node is the *leftson* of its parent node, and every odd-numbered node (except node 1) is the *rightson* of its parent node. Division by two (ignoring remainder) of the node number gives the parent node number. Nodes with sons are also called internal nodes, and nodes without sons are called terminal nodes. Figure A-5 on page A-54 illustrates schematically a 21-node tree with arrows drawn from each parent node to each son node.

A tree is used for merging several sorted sequences of records into a single merged sequence of records. At each step in the merging process, there exists the initial part of the merged sequence and the remaining parts of each of the sorted sequences that are being merged. Each step consists in selecting the lowest record (the record with the lowest key when sorting in ascending sequence) from all of the as yet unmerged parts of the sorted sequences and adding it to the merged sequence. Each terminal node in the tree represents one of the sorted sequences. The number of internal nodes in the tree is one less than the number of sorted sequences. Each internal node conceptually contains one record from each of the sorted sequences but one; these are the lowest records, from all but one of the sorted sequences, that have not yet been added to the merged sequence. In addition, there is the lowest record from the one remaining sorted sequence. This additional record is compared and interchanged with nodes of the tree to select the record to be added next to the merged sequence. This processing begins with the parent of the terminal node that represents the one remaining sorted sequence, and it continues from that node along the path to the root of the tree. The selected record emerges from the root of the tree.

The tree may perhaps be most easily explained by considering each node to represent a comparison operation in an “elimination tournament” to find the lowest record. After the tournament has been com-

pleted, each node has an associated “loser” record which had a higher key in the comparison represented by that node. Besides a loser record at each node, there is one record (the “winner”) which is not associated with any node since it never compared high. The next step would be to introduce a new record from the same sorted sequence from which the winner record originated and replay the tournament with the new record in place of the former winner. It can be seen that it is unnecessary to do all the comparisons represented by all the nodes in the tree — most of them are unaffected by the new record replacing the former winner. In fact, it is sufficient to redo only those node comparisons in which the former winner record participated. Each new record is inserted into the tree at the terminal node that represents the sorted sequence containing the record. The use of the tree assumes that programming provides a method of remembering at which terminal node each winning record originated. The instruction UPDATE TREE allows for a new record to be inserted at a terminal node and the tree to be updated so that a new winner record is left in the general registers.

Rather than comparing the actual keys of records, much of the merge logic can be performed using “codewords” to represent a record key rather than referring to actual keys. The value of a codeword at a node in the tree depends not only on the record’s key but also on the key of the winning record in the last comparison at that node. The codeword consists of two parts:

1. Bits 16-31 contain the one’s complement of the first halfword in which the record key differs from that of the node’s winning record.
2. Bits 0-15 specify the byte offset of the halfword in this record’s key just beyond the halfword value (complemented) in bit positions 16-31.

When comparing records in the path of the last winner record, if the new record is also represented by a codeword resulting from a comparison with the last winner, all codewords in the update path are with respect to the same winner. When comparing such codewords, a high codeword represents a low key and vice versa. Thus, when codewords are unequal, a node entry with a high codeword (representing a low actual key) should move up the tree.

In the case of a tie value of codewords, it is necessary to refer to the actual keys. This is done by the instruction COMPARE AND FORM CODEWORD, which resolves the ambiguity and computes a new codeword for the high-key (loser) record.

The eight bytes at each node of a tree consist of (1) a codeword for this record, computed with respect to the last record which compared low against this record and (2) a parameter usable to locate this record, for example, a direct or indirect address.

The instruction UPDATE TREE is so defined that tree updating stops after equal codewords are detected and the tie-breaking instruction COMPARE AND FORM CODEWORD can be used, after which UPDATE TREE can resume tree updating at the point where equal codewords were previously found.

COMPARE AND FORM CODEWORD may alternatively be used for merging in descending sequence. In that case, bits 16-31 of the codeword at a node contain the true value of the first halfword in which the record key differs from that of the node’s winning record. When the descending option of COMPARE AND FORM CODEWORD is used, the higher of two codewords represents the higher key.

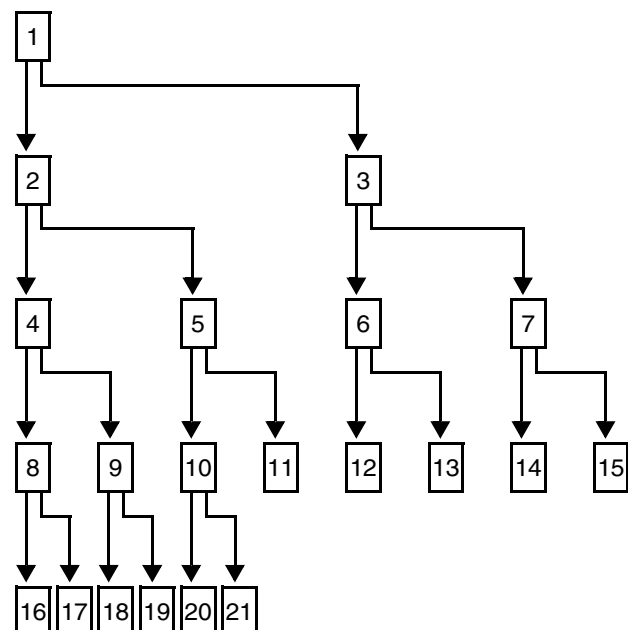

Figure A-5. Schematic Diagram of Merge Control Tree with 21 Nodes

## Example of Use of Sort Instructions

An example illustrates how the instructions UPDATE TREE and COMPARE AND FORM CODEWORD may be used in the merge operation within a sort program. A five-way merge requires a tree data structure with four internal nodes and five terminal-node positions. The schematic diagram shown later in this section illustrates such a tree, containing four internal nodes (not counting the dummy node) and five input sequences for a merge, one sequence at each terminal-node position. Each record in an input sequence in the diagram is indicated by its address. The actual record contents are shown in Figure A-7 on page A-58. Each record contains 16 bytes, consisting of the following fields:

| Byte Offset<br>(hexadecimal) | Field                                                                                                                                                  |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0-5                          | Six-byte record key.                                                                                                                                   |
| 6-7                          | Halfword node index specifying the input sequence of the next record of this input sequence.                                                           |
| 8-B                          | Address of the next record in the same input sequence.                                                                                                 |
| C-F                          | This chaining field is initially zero. At the completion of the merge, this field is to contain the address of the next record in the merged sequence. |

The merge process forms a single sorted sequence from five input sequences, each of which is in sorted order. This process can be subdivided into three steps:

1. A priming step takes the first record from each of the five input sequences and places them in the tree data structure. For each record to be introduced into the tree, first its codeword value is computed with respect to the lowest possible key value of all zeros. This codeword, with a second word which contains the address of the actual record, forms a doubleword node value that can be placed at the appropriate node. After priming, the node values, one each from each of the five input sequences, will have been placed in the tree so that each of the four internal nodes contains one node value and the node value for a winner record has emerged from the root of the tree.
2. After each winner emerges from the tree, the main merge process is performed repeatedly.

Each iteration introduces the node value for one new record into the tree and produces a node value for a new winner record. The tree plus the winner must at all times contain precisely one node value from each input sequence being merged. Therefore, the new node value that is introduced into the tree on each iteration must come from the same input sequence from which the winner node value in the preceding iteration originated.

3. When the node value for the last record of an input sequence emerges as a winner, there is no successor record from that input sequence to be introduced into the tree on the next iteration. Hence, the order of the merge must be reduced by one for each such occurrence. This runout process will consist of one or more iterations for each of a four-way, three-way, two-way, and one-way merge. The onset of runout occurs in the example when it is found that the next input record from a sequence is lower than its predecessor (a sequence break).

The priming process is discussed next, and the state of the tree is shown after priming is complete. Then, a short program that uses the instructions UPDATE TREE and COMPARE AND FORM CODEWORD to perform the main merge is described. An abbreviated trace is then presented to show the status of the tree and certain general registers for 16 iterations of the main merge. The runout process is not discussed in this example.

Priming begins by forming the node value for the first record of each input sequence. The first word of the node value is the codeword formed by executing COMPARE AND FORM CODEWORD on a record key containing all binary zeros. The second word of the node value is the address of the record represented by that node value. The node values for the first record of each input sequence are:

| Sequence Index | Node Values         |
|----------------|---------------------|
| 28             | 0006 FFFC 0000 1030 |
| 30             | 0006 FFFB 0000 1040 |
| 38             | 0006 FFFA 0000 1050 |
| 40             | 0004 FFFE 0000 1080 |
| 48             | 0006 FFF0 0000 1060 |

In the example, the tree data structure is assumed to have base address X'1000', which is kept in general register 4 (to match the expected use in UPDATE TREE). Similarly, internal-node index values and

input-sequence index values are always used from general register 5.

Although the tree-priming program is not part of this example, the UPDATE TREE instruction is used in creating it as follows. First, the codeword position for each internal node of the tree is initialized to all ones (X'FFFF FFFF'). This artifice fills the tree with dummy low records. Then, for each record in the table, (1) the sequence index is loaded into general register 5, (2) the node value is loaded into general registers 0 and 1, and (3) UPDATE TREE is executed. At the completion of this priming process, the tree-node contents in the example are as shown on line 0 of Figure A-9 on page A-60. The contents of the general registers are as shown on the first line of Figure A-8 on page A-59.

The figure illustrating the program for the main merge is divided into three groups of columns, containing the absolute program, the general-register trace, and the symbolic program. The first part of the program extends from symbolic locations L1 through L2; it introduces a new record into the tree and executes an UPDATE TREE instruction. If no tied codewords are encountered in UPDATE TREE, then the BRANCH ON CONDITION instruction following UPDATE TREE loops back to L1 to introduce the next record into the tree. This BRANCH ON CONDITION instruction is suitable for use when UPDATE TREE operates in accordance with either its method 1 (setting condition code 1) or its method 2 (setting condition code 3). (The preceding sentence applies to 370-XA. In ESA/370 and ESA/390, UPDATE TREE operates in accordance with only method 2, which is not to say that it cannot set condition code 1. Method 2, but not method 1, tests for the condition that sets condition code 3.)

If UPDATE TREE encounters tied codewords, then the UPDATE TREE instruction is completed, the subsequent BRANCH ON CONDITION instruction does not branch, and control falls through to the second part of the program, which handles entries with tied codewords. This part then branches back to UPDATE TREE at L2, which resumes the tree updating. It is possible for tied codewords to be encountered at any level in the tree (or indeed at all levels), so that the tied-codeword part of the program may be entered up to three times for each record introduced.

The general-register trace for the first part of the main merge shows the contents of the first seven general registers after each instruction is executed

during the first iteration. Note that the merged-chain field (at 1140) serves as the anchor for the merged-chain address chain through the records. The trace shows only the lower half of certain general registers, whose upper half is always zero.

Figure A-9 on page A-60 gives an abbreviated trace of the entire main merge of 16 records. For each record introduced into the tree, there are one or more lines (always an odd number) given in the figure to show the tree updating, which results finally in a winner in GR0 and GR1. The first line for each record shows the values of GR5, GR2, and GR3 before the first or only execution of UPDATE TREE. For the even-numbered lines, the storage updating by UPDATE TREE of tree nodes is shown (read left to right to follow the order of swapping). For example, consider line 10 and the corresponding UPDATE TREE: since GR5 contains 28, the first storage node examined is 1010 (refer to the schematic diagram). Since the codeword in GR0 is 0004 FFFE (same as for GR2), which is less than that of the word at 1010 (0006 FFF0), the doubleword at 1010 is swapped with that in GR0 and GR1. A second comparison at 1008 in the same execution of UPDATE TREE causes another register-storage doubleword swap, which leaves the winner (record 1040) in GR1 at the completion of UPDATE TREE (see the column at the far right of Figure A-9 on page A-60).

When a codeword comparison is made which does not result in a tie or a swap (that is, when the storage-codeword value is low), an asterisk appears in the trace for that storage entry.

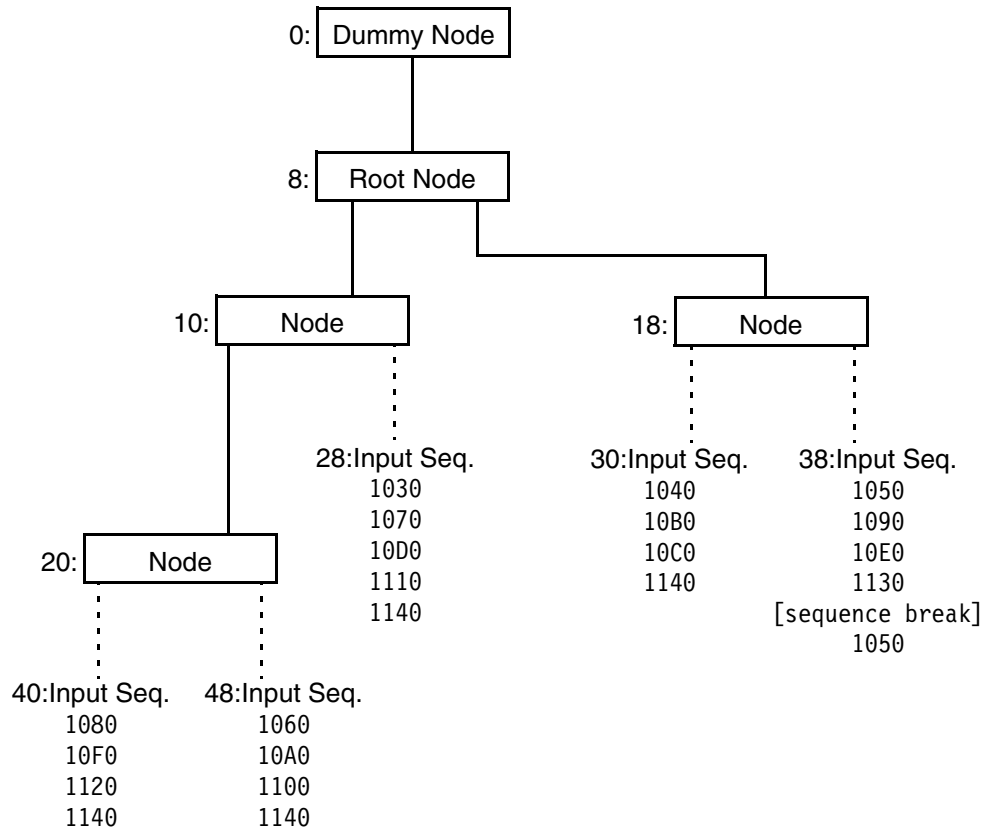

When equal codewords are found, the execution of UPDATE TREE is completed. The following line in each such case shows the result of the tied-codeword routine, which always stores a new codeword and may also store a new record address before branching back to L2 to execute UPDATE TREE again. In this line, the notation “loses” or “wins” means that the node loses or wins, respectively.

The tie-break trace part of Figure A-8 on page A-59 shows the treatment of the third record (that is, the first record for which UPDATE TREE encounters a tied codeword). This corresponds to line 31 in Figure A-9 on page A-60.

The following is a summary of the steps that are needed to use this example for verification purposes:

1. Initialize storage as follows:

- a. 1008 through 102F from line 0 of Figure A-9 on page A-60
  - b. 1030 through 114F from Figure A-7 on page A-58
  - c. 1150 through 1189 from Figure A-8 on page A-59
2. Initialize GRs per first line in Figure A-8 and trace first record per Figure A-8.
  3. Trace to completion of each UPT or BC 15,L2 (once for each line of Figure A-9). A detailed trace of the GRs for the tied-codeword part of line 31 of Figure A-9 is given in the lower part of Figure A-8.
  4. Verify that addresses in the chain beginning at 103C and continuing through 114C are as shown in the right-hand column of Figure A-7.

**Note:** Each node and input sequence is identified by a number which is the hexadecimal node index. Each input sequence is given as a list of record addresses (also in hexadecimal).

Figure A-6. Schematic Diagram for Example of Merge to Be Performed

| Location | Record Key at Hex Byte Offset |         |         |         |         |         | Successor Record |         |          |   |   |   | Merged-Chain Address |   |   |   |
|----------|-------------------------------|---------|---------|---------|---------|---------|------------------|---------|----------|---|---|---|----------------------|---|---|---|
|          |                               |         |         |         |         |         | Index            |         | Location |   |   |   |                      |   |   |   |
|          | 0                             | 1       | 2       | 3       | 4       | 5       | 6                | 7       | 8        | 9 | A | B | C                    | D | E | F |
| 1030     | 0 0 0 0                       | 0 0 0 0 | 0 0 0 3 | 0 0 2 8 | 0 0 0 0 | 1 0 7 0 | 0 0 0 0          | 1 0 4 0 |          |   |   |   |                      |   |   |   |
| 1040     | 0 0 0 0                       | 0 0 0 0 | 0 0 0 4 | 0 0 3 0 | 0 0 0 0 | 1 0 B 0 | 0 0 0 0          | 1 0 5 0 |          |   |   |   |                      |   |   |   |
| 1050     | 0 0 0 0                       | 0 0 0 0 | 0 0 0 5 | 0 0 3 8 | 0 0 0 0 | 1 0 9 0 | 0 0 0 0          | 1 0 6 0 |          |   |   |   |                      |   |   |   |

#### Explanation:

<sup>1</sup> Line 0 shows the values in the tree after it is primed.

\* Means no swap.

\*\* Means no swap if UPDATE TREE method 1 is used or no examination if UPDATE TREE method 2 is used. Only method 2 is included in ESA/370 and ESA/390.

CC = 0 UPDATE TREE finds a tie and sets condition code 0.

Loses The tied-codeword routine finds that the node loses.

Wins The tied-codeword routine finds that the node wins.

Equal The tied-codeword routine finds that the keys are equal.

Branch Branches to terminate at 118A on sequence break.

No comp No compare.

Figure A-9. Abbreviated Trace of Main Merge Processing

## Appendix B. Lists of Instructions

The following figures list instructions by name, mnemonic, and operation code. Some models may offer instructions that do not appear in the figures, such as those provided for assists or as part of special or custom features.

The operation code for the interpretive execution facility is not included in this appendix. See the publication *IBM System/370 Extended Architecture Interpretive Execution*, SA22-7095, for the operation code associated with that facility.

The operation code 00 hex with a two-byte instruction format is allocated for use by the program when an indication of an invalid operation is required. Operation code 00 hex will never be assigned to an instruction implemented in the CPU.

### Explanation of Symbols in “Characteristics” and “Page” Columns:

|                |                                                                                                                                                                                                                                                                                                                                               |

Figure B-3. Instructions Arranged by Operation Code (Part 22 of 22)

## Appendix C. Condition-Code Settings

This appendix lists the condition-code setting for instructions in z/Architecture which set the condition code. In addition to those instructions listed which set the condition code, the condition code may be changed by DIAGNOSE and the target of EXECUTE. The condition code is loaded by LOAD PSW, LOAD PSW EXTENDED, PROGRAM RETURN, RESUME PROGRAM, and SET PROGRAM MASK and by an

interruption. The condition code is set to zero by initial CPU reset and is loaded by the successful conclusion of the initial-program-loading sequence.

Some models may offer instructions which set the condition code and do not appear in this document, such as those provided for assists or as part of special or custom features.

| Instruction                            | Condition Code     |                           |                           |                           |
|----------------------------------------|--------------------|---------------------------|---------------------------|---------------------------|
|                                        | 0                  | 1                         | 2                         | 3                         |
| ADD (BFP, DFP)                         | Zero               | < zero                    | > zero                    | NaN                       |
| ADD (general)                          | Zero               | < zero                    | > zero                    | Overflow                  |
| ADD DECIMAL                            | Zero               | < zero                    | > zero                    | Overflow                  |
| ADD HALFWORD                           | Zero               | < zero                    | > zero                    | Overflow                  |

Figure C-1. Summary of Condition-Code Settings (Part 6 of 7)

| Instruction                   | Condition Code                                                                                                                                                                                                                                                                                        |   |   |   |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---|---|---|
|                               | 0                                                                                                                                                                                                                                                                                                     | 1 | 2 | 3 |
| <b>Explanation and Notes:</b> |                                                                                                                                                                                                                                                                                                       |   |   |   |
| —                             | Code is not set by the instruction.                                                                                                                                                                                                                                                                   |   |   |   |
| 1                             | For DIAGNOSE, the resulting condition code is model-dependent.                                                                                                                                                                                                                                        |   |   |   |
| 2                             | For LOAD REAL ADDRESS, condition code 3 is set if address-space-control element not available, region-table entry outside table or invalid, segment-table entry outside table, or, for LRA in 24- or 31-bit mode when bits 0-32 of entry address not all zeros, segment- or page-table entry invalid. |   |   |   |
| 3                             | For LOAD PSW, LOAD PSW EXTENDED, and RESUME PROGRAM, the condition code is loaded from the condition-code field of the second operand.                                                                                                                                                                |   |   |   |
| 4                             | For SET PROGRAM MASK, the condition code is loaded from bit positions 2 and 3 of the first operand.                                                                                                                                                                                                   |   |   |   |
| 5                             | For various vector-facility instructions, the condition code is optionally set based on the CS control in the M <sub>5</sub> field of the instruction.                                                                                                                                                |   |   |   |

## Appendix H. Hexadecimal Tables

The following tables aid in converting hexadecimal values to decimal values, or the reverse.

### ***Direct Conversion Table***

This table provides direct conversion of decimal and hexadecimal numbers in these ranges:

**Hexadecimal**  
000 to FFF

**Decimal**  
0000 to 4095

To convert numbers outside these ranges, and to convert fractions, use the hexadecimal and decimal conversion tables that follow the direct conversion table in this appendix.

|     | 0    | 1    | 2    | 3    | 4    | 5    | 6    | 7    | 8    | 9    | A    | B    | C    | D    | E    | F    |

| F   | 4,026,531,840 | F   | 251,658,240 | F   | 15,728,640 | F   | 983,040 | F   | 61,440  | F   | 3,840   | F   | 240     | F   | 15      |
| 8   |               | 7   |             | 6   |            | 5   |         | 4   |         | 3   |         | 2   |         | 1   |         |

### TO CONVERT HEXADECIMAL TO DECIMAL

1. Locate the column of the decimal numbers corresponding to the leftmost digit or letter of the hexadecimal; select from this column and record the number that corresponds to the position of the hexadecimal digit or letter.
2. Repeat step 1 for the next (second from the left) position.
3. Repeat step 1 for the units (third from the left) position.
4. Add the numbers selected from the table to form the decimal number.

#### EXAMPLE

|                                 |  |            |
|---------------------------------|--|------------|
| Conversion of Hexadecimal Value |  | D34        |
| 1. D                            |  | 3328       |
| 2. 3                            |  | 48         |
| 3. 4                            |  | <u>+ 4</u> |
| 4. Decimal                      |  | 3380       |

To convert integer numbers greater than the capacity of the table, use the techniques below:

#### HEXADECIMAL TO DECIMAL

Successive cumulative multiplication from left to right, adding units position.

Example:  $D34_{16} = 3380_{10}$

$$\begin{array}{r}
 D = 13 \\
 \times 16 \\
 \hline
 208 \\
 3 = + 3 \\
 \hline
 211 \\
 \times 16 \\
 \hline
 3376 \\
 4 = + 4 \\
 \hline
 3380
 \end{array}$$

### TO CONVERT DECIMAL TO HEXADECIMAL

1. (a) Select from the table the highest decimal number that is equal to or less than the number to be converted.  
(b) Record the hexadecimal of the column containing the selected number.  
(c) Subtract the selected decimal from the number to be converted.
2. Using the remainder from step 1(c), repeat all of step 1 to develop the second position of the hexadecimal (and a remainder)
3. Using the remainder from step 2, repeat all of step 1 to develop the units position of the hexadecimal.
4. Combine the terms to form the hexadecimal number.

#### EXAMPLE

|                             |  |              |
|-----------------------------|--|--------------|
| Conversion of Decimal Value |  | 3380         |
| 1. D                        |  | <u>-3328</u> |
|                             |  | 52           |
| 2. 3                        |  | <u>- 48</u>  |
|                             |  | 4            |
| 3. 4                        |  | <u>- 4</u>   |
| 4. Hexadecimal              |  | D34          |

#### DECIMAL TO HEXADECIMAL

Divide and collect the remainder in reverse order

Example:  $3380_{10} = X_{16}$

$$\begin{array}{rcl}
 16 \overline{) 3380} & \rightarrow & 4 \\
 16 \overline{) 211} & \rightarrow & 3 \\
 16 \overline{) 13} & \rightarrow & D
 \end{array}$$

Remainder ↑

$3380_{10} = D34_{16}$

### POWERS OF 16 TABLE

Example:  $268,435,456_{10} = (2.68435456 \times 10^8)_{10} = 1000\ 0000_{16} = (10^7)_{16}$

| $16^n$      | n |
|-------------|---|
| 1           | 0 |
| 16          | 1 |
| 256         | 2 |
| 4 096       | 3 |
| 65 536      | 4 |
| 1 048 576   | 5 |
| 16 777 216  | 6 |
| 268 435 456 | 7 |

| $16^n$                    | n      |
|---------------------------|--------|
| 4 294 967 296             | 8      |
| 68 719 476 736            | 9      |
| 1 099 511 627 776         | 10 = A |
| 17 592 186 044 416        | 11 = B |
| 281 474 976 710 656       | 12 = C |
| 4 503 599 627 370 496     | 13 = D |
| 72 057 594 037 927 936    | 14 = E |
| 1 152 921 504 606 846 976 | 15 = F |

### TO CONVERT .ABC HEXADECIMAL TO DECIMAL

Find .A in position 1 .6250  
 Find .0B in position 2 .0429 6825  
 Find .00C in position 3 + .0029 2968 7500  
 .ABC is equal to .6708 9843 7500

### TO CONVERT .13 DECIMAL TO HEXADECIMAL

- Find .1250 next lowest to .1300  
 subtract  $-.1250$  = .2 Hex
- Find .0039 0625 next lowest to .0050 0000  
 subtract  $-.0039 0625$  = .01
- Find .0009 7656 2500 .0010 9375 0000  
 subtract  $-.0009 7656 2500$  = .004
- Find .0001 0681 1523 4375 .0001 1718 7500 0000  
 subtract  $-.0001 0681 1523 4375$  = .0007  
 .0000 1037 5976 5625 = .2147 Hex
- .13 Decimal is approximately equal to  $\xrightarrow{\quad\quad\quad}$

To convert fractions beyond the capacity of the table, use techniques below:

### HEXADECIMAL TO FRACTION DECIMAL

Convert the hexadecimal fraction to its decimal equivalent using the same technique as for integer numbers. Divide the results by  $16^n$  (n is the number of fraction positions).

Example:  $.8A7_{16} = .540771_{10}$   
 $8A7_{16} = 2215_{10}$   
 $16^3 = 4096$        $4096 \overline{) 2215.000000}$

### DECIMAL FRACTION TO HEXADECIMAL

Collect integer parts of product in the order of calculation.

Example:  $.5408_{10} = .8A7_{16}$

$$\begin{array}{r}
 .5408 \\
 \times 16 \\
 \hline
 8 \leftarrow 8.6528 \\
 \times 16 \\
 \hline
 A \leftarrow 10.4448 \\
 \times 16 \\
 \hline
 7 \leftarrow 7.1168
 \end{array}$$

### Hexadecimal Addition and Subtraction Table

Example:  $6 + 2 = 8$ ,  $8 - 2 = 6$ , and  $8 - 6 = 2$

|   | 1  | 2  | 3  | 4  | 5  | 6  | 7  | 8  | 9  | A  | B  | C  | D  | E  | F  |

## Numerics

2K-IDAW control 15-28

370-XA architecture 1-29

## A

A (ADD) binary instruction 7-25

abort

    transactional execution 5-90

aborted-transaction-instruction-address

    in the transaction diagnostic block 5-96

absolute address 3-4

absolute storage 3-4

access-control bits

    in segment-table entry 3-43, 3-46

access-control bits in storage key 3-9

access-exception-fetch/store-indication facility

    facility indication 4-77

access exceptions 6-45, 6-51

    priority of 6-51

    recognition of 6-45

access key 3-11

    for channel-program execution 3-11, 15-25,  
    15-30

    for channel-subsystem monitoring 3-11

    for CPU 3-11

access list 5-57

*See also* access-list entry

    accessing capability, revocation of 5-52

    allocation and invalidation of entries in 5-50

    authorizing the use of entries in 5-50

    concepts 5-48

    designation (ALD) 5-57

    length (ALL) 5-57

    origin (ALO) 5-57

access-list-controlled protection 3-13

    exception for 6-33

access-list designation 5-57

access-list entry (ALE) 5-57

    authorization index (ALEAX) 5-58

    number

*See* ALEN

    sequence exception 6-21

        as an access exception 6-45

    sequence number (ALESN)

        in ALE 5-57

        in ALET 5-55

    token

*See* ALET

access-register mode 3-37

access-register translation (ART) 5-54

    as part of LOAD REAL ADDRESS, STORE REAL  
    ADDRESS, TEST ACCESS, and TEST  
    PROTECTION 5-60

    introduction to 5-48

    lookaside buffer

     7-236  
 LLIHH (LOAD LOGICAL IMMEDIATE) instruction  
     7-236  
 LLIHL (LOAD LOGICAL IMMEDIATE) instruction  
     7-236  
 LLILF (LOAD LOGICAL IMMEDIATE) instruction  
     7-236  
 LLILH (LOAD LOGICAL IMMEDIATE) instruction  
     7-236  
 LLILL (LOAD LOGICAL IMMEDIATE) instruction  
     7-236  
 LLTG (LOAD AND TRAP) instruction 7-228  
 LLTGF (LOAD LOGICAL AND TRAP) instruction  
     7-234  
 LLTGT (LOAD LOGICAL THIRTY ONE BITS AND  
     TRAP) instruction 7-237

LLZRGF (LOAD LOGICAL AND ZERO RIGHTMOST BYTE) binary instruction 7-234  
 LM (LOAD MULTIPLE) instruction 7-237  
 LMD (LOAD MULTIPLE DISJOINT) instruction 7-238  
 LMG (LOAD MULTIPLE) instruction 7-237  
 LMH (LOAD MULTIPLE HIGH) instruction 7-238  
 LMY (LOAD MULTIPLE) instruction 7-237  
 LNDBR (LOAD NEGATIVE) BFP instruction 19-34  
 LNDFR (LOAD NEGATIVE) floating-point-support instruction 9-34  
 LNDR (LOAD NEGATIVE) HFP instruction 18-16  
 LNEBR (LOAD NEGATIVE) BFP instruction 19-34  
 LNER (LOAD NEGATIVE) HFP instruction 18-16  
 LNGFR (LOAD NEGATIVE) binary instruction 7-239  
 LNGR (LOAD NEGATIVE) binary instruction 7-239  
 LNR (LOAD NEGATIVE) binary instruction 7-239  
 LNXBR (LOAD NEGATIVE) BFP instruction 19-34  
 LNXR (LOAD NEGATIVE) HFP instruction 18-16  
 LOAD ACCESS MULTIPLE instructions 7-222  
 LOAD ADDRESS EXTENDED instruction 7-223  
 LOAD ADDRESS instructions 7-223  
     examples A-23  
 LOAD ADDRESS RELATIVE LONG instruction 7-224  
 LOAD ADDRESS SPACE PARAMETERS instruction 10-39  
 LOAD AND ADD instructions 7-225  
 LOAD AND ADD LOGICAL instructions 7-225  
 LOAD AND AND instructions 7-226  
 LOAD AND EXCLUSIVE OR instructions 7-226  
 LOAD AND OR instructions 7-227  
 LOAD AND TEST BFP instructions 19-31  
 LOAD AND TEST binary instruction 7-228  
 LOAD AND TEST DFP instructions 20-40  
 LOAD AND TEST HFP instructions 18-13  
 LOAD AND TRAP binary instructions 7-228  
 load-and-trap facility 1-16  
     facility indication 4-77  
 LOAD AND ZERO RIGHTMOST BYTE binary instructions 7-229  
 load-and-zero-rightmost-byte facility 1-16  
     facility indication 4-77  
 LOAD binary instructions 7-221  
     example A-23  
 LOAD BYTE HIGH instruction 7-229  
 LOAD BYTE instructions 7-229  
 load-clear key 12-3  
 load-clear-list-directed key 12-4  
 LOAD COMPLEMENT BFP instructions 19-31  
 LOAD COMPLEMENT binary instruction 7-230  
 LOAD COMPLEMENT floating-point-support instruction 9-31  
 LOAD COMPLEMENT HFP instructions 18-14  
 LOAD CONTROL instructions 10-49  
 LOAD COUNT TO BLOCK BOUNDARY binary instruction 7-230  
 LOAD floating-point-support instructions 9-31  
 LOAD FP INTEGER BFP instructions 19-32  
 LOAD FP INTEGER DFP instructions 20-41  
 LOAD FP INTEGER HFP instructions 18-15  
 LOAD FPC AND SIGNAL floating-point-support instruction 9-32  
 LOAD FPC floating-point-support instruction 9-31  
 LOAD FPR FROM GR floating-point-support instruction 9-34  
 LOAD GR FROM FPR floating-point-support instruction 9-34  
 LOAD HALFWORD binary 7-231  
 LOAD HALFWORD HIGH IMMEDIATE ON CONDITION binary instruction 7-232  
 LOAD HALFWORD HIGH instruction 7-232  
 LOAD HALFWORD IMMEDIATE instruction 7-231  
 LOAD HALFWORD IMMEDIATE ON CONDITION binary instruction 7-232  
 LOAD HALFWORD instruction  
     examples A-24  
 LOAD HALFWORD RELATIVE LONG instructions 7-231  
 LOAD HIGH AND TRAP instruction 7-233  
 LOAD HIGH instruction 7-233  
 LOAD HIGH ON CONDITION instructions 7-239  
 LOAD IMMEDIATE instruction 7-222  
 load indicator 12-3  
 LOAD LENGTHENED BFP instructions 19-33  
 LOAD LENGTHENED DFP instructions 20-44  
 LOAD LENGTHENED HFP instructions 18-15  
 LOAD LOGICAL AND TRAP instruction 7-234  
 LOAD LOGICAL AND ZERO RIGHTMOST BYTE binary instruction 7-234  
 LOAD LOGICAL CHARACTER HIGH instruction 7-235  
 LOAD LOGICAL CHARACTER instructions 7-234  
 LOAD LOGICAL HALFWORD HIGH instruction 7-236  
 LOAD LOGICAL HALFWORD instructions 7-235  
 LOAD LOGICAL HALFWORD RELATIVE LONG instructions 7-235  
 LOAD LOGICAL IMMEDIATE instructions 7-236  
 LOAD LOGICAL instructions 7-233  
 LOAD LOGICAL RELATIVE LONG binary instruction 7-233  
 LOAD LOGICAL THIRTY ONE BITS AND TRAP instruction 7-237  
 LOAD LOGICAL THIRTY ONE BITS instructions 7-237  
 LOAD MULTIPLE DISJOINT instruction 7-238  
 LOAD MULTIPLE HIGH instruction 7-238  
 LOAD MULTIPLE instructions 7-237

- LOAD NEGATIVE BFP instructions 19-34

- type of PROGRAM CALL 5-38

## U

- UIB
  - See UTC information block 4-51
- ulp (unit in the last place) 9-7, 9-8, 19-3
- underflow
  - See exponent underflow
- unit check (device status)
  - in establishing dedicated allegiance 15-13
- unit of operation 5-24
- unlock A-47
  - example with FIFO queuing A-50
  - example with LIFO queuing A-49
- unnormalized floating-point number 18-2

- HFP data only 9-4
- unordered (comparison to a NaN) 9-24
- UNPACK ASCII instruction 7-367
- UNPACK instruction 7-366
  - example A-35
- UNPACK UNICODE instruction 7-367
- UNPK (UNPACK) instruction 7-366
  - example A-35
- UNPKA (PACK ASCII) instruction 7-367
- UNPKU (PACK UNICODE) instruction 7-367
- unprivileged instructions 4-5, 7-3
- unsigned binary
  - arithmetic 7-6
  - integer 7-4
    - examples A-3
    - in address generation 5-11
- unsigned binary integer
  - conversion to floating point 19-21
- unsigned-packed-decimal format 8-2
  - used in DFP formatting instructions 20-8
- unsigned scaling exponent ( $\alpha$ ) 9-12
- unsolicited interruption condition (I/O) 16-3
- unstack-suppression bit 5-80
- unstacking process 5-87
- update reference 5-122
- UPDATE TREE instruction 7-368
  - example A-53
- UPT (UPDATE TREE) instruction 7-368
  - example A-53
- usable ALB entry 5-66
- UTC (Coordinated Universal Time) used in TOD epoch 4-45
- UTC information block (UIB) 4-51

## V

- VA (VECTOR ADD) vector instruction 22-3
- VAC (VECTOR ADD WITH CARRY) vector instruction 22-4
- VACC (VECTOR ADD COMPUTE CARRY) vector instruction 22-4
- VACCC (VECTOR ADD WITH CARRY COMPUTE CARRY) vector instruction 22-5
- valid ART-table entry 5-66
- valid CBC 11-2
- valid floating-point-register numbers 9-9
- valid region-table, segment-table, or page-table entry 3-59
- validation 11-6
  - of registers 11-9
  - of storage 11-7
  - of storage key 11-7
  - of TOD clock 11-9
- validity bit for backward stack-entry address 5-81

- validity bit for forward-section-header address 5-82
- validity bits
  - in machine-check-interruption code 11-19
  - in subchannel logout 16-49
- variable-length field 3-3
- VAVG (VECTOR AVERAGE) vector instruction 22-5
- VAVGL (VECTOR AVERAGE LOGICAL) vector instruction 22-6
- VCDG (VECTOR FP CONVERT FROM FIXED 64-BIT) vector instruction 24-13
- VCDLG (VECTOR FP CONVERT FROM LOGICAL 64-BIT) vector instruction 24-15
- VCEQ (VECTOR COMPARE EQUAL) vector instruction 22-7
- VCGD (VECTOR FP CONVERT TO FIXED 64-BIT) vector instruction 24-16
- VCH (VECTOR COMPARE HIGH) vector instruction 22-8
- VCHL (VECTOR COMPARE HIGH LOGICAL) vector instruction 22-9
- VCKSM (VECTOR CHECKSUM) vector instruction 22-6
- VCLGD (VECTOR FP CONVERT TO LOGICAL 64-BIT) vector instruction 24-18
- VCLZ (VECTOR COUNT LEADING ZEROS) vector instruction 22-10
- VCTZ (VECTOR COUNT TRAILING ZEROS) vector instruction 22-10
- VEC (VECTOR ELEMENT COMPARE) vector instruction 22-7
- VECL (VECTOR ELEMENT COMPARE LOGICAL) vector instruction 22-7
- vector
  - registers 2-5
  - validity bit for 11-20
- VECTOR ADD COMPUTE CARRY vector instruction 22-4
- VECTOR ADD vector instruction 22-3
- VECTOR ADD WITH CARRY COMPUTE CARRY vector instruction 22-5
- VECTOR ADD WITH CARRY vector instruction 22-4
- VECTOR AND vector instruction 22-5
- VECTOR AND WITH COMPLEMENT vector instruction 22-5
- VECTOR AVERAGE LOGICAL vector instruction 22-6
- VECTOR AVERAGE vector instruction 22-5
- VECTOR CHECKSUM vector instruction 22-6
- VECTOR COMPARE EQUAL vector instruction 22-7
- VECTOR COMPARE HIGH LOGICAL vector instruction 22-9
- VECTOR COMPARE HIGH vector instruction 22-8
- VECTOR COUNT LEADING ZEROS vector instruction 22-10
- VECTOR COUNT TRAILING ZEROS vector instruction 22-10
- VECTOR ELEMENT COMPARE LOGICAL vector instruction 22-7
- VECTOR ELEMENT COMPARE vector instruction 22-7
- VECTOR ELEMENT ROTATE AND INSERT UNDER MASK vector instruction 22-20
- VECTOR ELEMENT ROTATE LEFT LOGICAL vector instruction 22-19
- VECTOR ELEMENT SHIFT LEFT vector instruction 22-21
- VECTOR ELEMENT SHIFT RIGHT ARITHMETIC vector instruction 22-22
- VECTOR ELEMENT SHIFT RIGHT LOGICAL vector instruction 22-22

- VECTOR EXCLUSIVE OR vector instruction 22-11
- vector facility for z/Architecture
  - facility indication 4-78
- vector facility for z/architecture 1-23
- VECTOR FIND ANY ELEMENT EQUAL vector instruction 23-1
- VECTOR FIND ELEMENT EQUAL vector instruction 23-3
- VECTOR FIND ELEMENT NOT EQUAL vector instruction 23-4
- VECTOR FP ADD vector instruction 24-3
- VECTOR FP COMPARE AND SIGNAL SCALAR vector instruction 24-8
- VECTOR FP COMPARE EQUAL vector instruction 24-9
- VECTOR FP COMPARE HIGH OR EQUAL vector instruction 24-12
- VECTOR FP COMPARE HIGH vector instruction 24-10
- VECTOR FP COMPARE SCALAR vector instruction 24-7
- VECTOR FP CONVERT FROM FIXED 64-BIT vector instruction 24-13
- VECTOR FP CONVERT FROM LOGICAL 64-BIT vector instruction 24-15
- VECTOR FP CONVERT TO FIXED 64-BIT vector instruction 24-16
- VECTOR FP CONVERT TO LOGICAL 64-BIT vector instruction 24-18
- VECTOR FP DIVIDE vector instruction 24-20
- VECTOR FP LOAD LENGTHENED vector instruction 24-24
- VECTOR FP LOAD ROUNDED vector instruction 24-25
- VECTOR FP MULTIPLY AND ADD vector instruction 24-27

VECTOR FP MULTIPLY AND SUBTRACT vector instruction 24-27  
 VECTOR FP MULTIPLY vector instruction 24-26  
 VECTOR FP PERFORM SIGN OPERATION vector instruction 24-29  
 VECTOR FP SQUARE ROOT vector instruction 24-30  
 VECTOR FP SUBTRACT vector instruction 24-31  
 VECTOR FP TEST DATA CLASS IMMEDIATE vector instruction 24-31  
 VECTOR GALOIS FIELD MULTIPLY SUM AND ACCUMULATE vector instruction 22-11  
 VECTOR GALOIS FIELD MULTIPLY SUM vector instruction 22-11  
 VECTOR GATHER ELEMENT vector instruction 21-4  
 VECTOR GENERATE BYTE MASK vector instruction 21-4  
 VECTOR GENERATE MASK vector instruction 21-4  
 VECTOR ISOLATE STRING vector instruction 23-5  
 VECTOR LOAD AND REPLICATE vector instruction 21-5  
 VECTOR LOAD COMPLEMENT vector instruction 22-12  
 VECTOR LOAD ELEMENT IMMEDIATE vector instruction 21-6  
 VECTOR LOAD ELEMENT vector instruction 21-6  
 VECTOR LOAD FP INTEGER vector instruction 24-22  
 VECTOR LOAD GR FROM VR ELEMENT vector instruction 21-7  
 VECTOR LOAD LOGICAL ELEMENT AND ZERO vector instruction 21-7  
 VECTOR LOAD MULTIPLE vector instruction 21-8  
 VECTOR LOAD POSITIVE vector instruction 22-12  
 VECTOR LOAD TO BLOCK BOUNDARY vector instruction 21-8  
 VECTOR LOAD vector instruction 21-5  
 VECTOR LOAD VR ELEMENT FROM GR vector instruction 21-9  
 VECTOR LOAD VR FROM GRS DISJOINT vector instruction 21-9  
 VECTOR LOAD WITH LENGTH vector instruction 21-10  
 VECTOR MAXIMUM LOGICAL vector instruction 22-13  
 VECTOR MAXIMUM vector instruction 22-13  
 VECTOR MERGE HIGH vector instruction 21-10  
 VECTOR MERGE LOW vector instruction 21-10  
 VECTOR MINIMUM LOGICAL vector instruction 22-13  
 VECTOR MINIMUM vector instruction 22-13  
 VECTOR MULTIPLY AND ADD EVEN vector instruction 22-15  
 VECTOR MULTIPLY AND ADD HIGH vector instruction 22-14  
 VECTOR MULTIPLY AND ADD LOGICAL EVEN vector instruction 22-15  
 VECTOR MULTIPLY AND ADD LOGICAL HIGH vector instruction 22-15  
 VECTOR MULTIPLY AND ADD LOGICAL ODD vector instruction 22-16  
 VECTOR MULTIPLY AND ADD LOW vector instruction 22-14  
 VECTOR MULTIPLY AND ADD ODD vector instruction 22-16  
 VECTOR MULTIPLY EVEN vector instruction 22-17  
 VECTOR MULTIPLY HIGH vector instruction 22-16  
 VECTOR MULTIPLY LOGICAL EVEN vector instruction 22-18  
 VECTOR MULTIPLY LOGICAL HIGH vector instruction 22-16  
 VECTOR MULTIPLY LOGICAL ODD vector instruction 22-18  
 VECTOR MULTIPLY LOW vector instruction 22-17  
 VECTOR MULTIPLY ODD vector instruction 22-18  
 VECTOR NOR vector instruction 22-19  
 VECTOR OR vector instruction 22-19  
 VECTOR PACK LOGICAL SATURATE vector instruction 21-12  
 VECTOR PACK SATURATE vector instruction 21-11  
 VECTOR PACK vector instruction 21-11  
 VECTOR PERMUTE DOUBLEWORD IMMEDIATE vector instruction 21-13  
 VECTOR PERMUTE vector instruction 21-13  
 VECTOR POPULATION COUNT vector instruction 22-19  
 VECTOR REPLICATE IMMEDIATE vector instruction 21-14  
 VECTOR REPLICATE vector instruction 21-14  
 VECTOR SCATTER ELEMENT vector instruction 21-15  
 VECTOR SELECT vector instruction 21-15  
 VECTOR SHIFT LEFT BY BYTE vector instruction 22-23  
 VECTOR SHIFT LEFT DOUBLE BY BYTE vector instruction 22-23  
 VECTOR SHIFT LEFT vector instruction 22-23  
 VECTOR SHIFT RIGHT ARITHMETIC BY BYTE vector instruction 22-24  
 VECTOR SHIFT RIGHT ARITHMETIC vector instruction 22-24  
 VECTOR SHIFT RIGHT LOGICAL BY BYTE vector instruction 22-24  
 VECTOR SHIFT RIGHT LOGICAL vector instruction 22-24  
 VECTOR SIGN EXTEND TO DOUBLEWORD vector instruction 21-15

VECTOR STORE ELEMENT vector instruction 21-16  
 VECTOR STORE MULTIPLE vector instruction 21-17  
 VECTOR STORE vector instruction 21-16  
 VECTOR STORE WITH LENGTH vector instruction 21-17  
 VECTOR STRING RANGE COMPARE vector instruction 23-6  
 VECTOR SUBTRACT COMPUTE BORROW INDICATION vector instruction 22-25  
 VECTOR SUBTRACT vector instruction 22-25  
 VECTOR SUBTRACT WITH BORROW COMPUTE BORROW INDICATION vector instruction 22-26  
 VECTOR SUBTRACT WITH BORROW INDICATION vector instruction 22-26  
 VECTOR SUM ACROSS DOUBLEWORD vector instruction 22-27  
 VECTOR SUM ACROSS QUADWORD vector instruction 22-27  
 VECTOR SUM ACROSS WORD vector instruction 22-27  
 VECTOR TEST UNDER MASK vector instruction 22-28

VSTM (VECTOR STORE MULTIPLE) vector instruction 21-17

VSTRC (VECTOR STRING RANGE COMPARE) vector instruction 23-6

VSUM (VECTOR SUM ACROSS WORD) vector instruction 22-27

VSUMG (VECTOR SUM ACROSS DOUBLEWORD) vector instruction 22-27

VSUMQ (VECTOR SUM ACROSS QUADWORD) vector instruction 22-27

VTAM use of symbol translation 7-160

VTM (VECTOR TEST UNDER MASK) vector instruction 22-28

VUPH (VECTOR UNPACK HIGH) vector instruction 21-17

VUPL (VECTOR UNPACK LOW) vector instruction 21-18

VUPLH (VECTOR UNPACK LOGICAL) vector instruction 21-18

VUPLL (VECTOR UNPACK LOGICAL LOW) vector instruction 21-19

VX (VECTOR EXCLUSIVE OR) vector instruction 22-11

VXC (vector-exception code) 6-19

## W

wait indicator 12-6

wait-state bit  
in the PSW 4-5

warning (machine-check condition) 11-16  
subclass-mask bit for 11-25

warning-track-interruption facility 1-23

WFC (VECTOR FP COMPARE SCALAR) vector instruction 24-7

WFK (VECTOR FP COMPARE AND SIGNAL SCALAR) vector instruction 24-8

word 3-3

word-concurrent storage references 5-124

working allegiance (I/O) 15-12

wraparound  
of instruction addresses 5-10  
of PER addresses 4-32  
of register numbers  
for LOAD MULTIPLE instruction 7-238  
for STORE MULTIPLE instruction 7-335  
of storage addresses 3-7  
controlled by addressing mode 3-7  
for MOVE INVERSE instruction 7-245  
for MOVE LONG EXTENDED instruction 7-250  
for MOVE LONG instruction 7-246  
for MOVE LONG UNICODE instruction 7-254  
for MOVE WITH OPTIONAL SPECIFICATIONS instruction 10-67  
of TOD clock 4-41

## X

X (EXCLUSIVE OR) instruction 7-212

X field of instruction 5-11

XA (extended architecture)  
*See* 370-XA architecture

XC (EXCLUSIVE OR) instruction 7-213  
examples A-20

XG (EXCLUSIVE OR) instruction 7-212

XGR (EXCLUSIVE OR) instruction 7-212

XI (EXCLUSIVE OR) instruction 7-213  
example A-21

XIHF (EXCLUSIVE OR IMMEDIATE) instruction 7-214

XILF (EXCLUSIVE OR IMMEDIATE) instruction 7-214

XIY (EXCLUSIVE OR) instruction 7-213

XR (EXCLUSIVE OR) instruction 7-212

XRK (EXCLUSIVE OR) binary instruction 7-212

XSCH (CANCEL SUBCHANNEL) instruction 14-3  
XY (EXCLUSIVE OR) instruction 7-212

## **Z**

Z bit (zero condition-code bit) 16-12  
    as cause of intermediate interruption condition  
    16-18  
z/Architecture architecture  
    additions to 1-2, 1-7  
    original highlights of 1-2  
ZAP (ZERO AND ADD) instruction 8-14  
    example A-41  
zero  
    instruction-length code 6-7  
    negative

    See negative zero  
    normal meaning for byte value xxvii  
    setting floating-point register to 9-35  
    true (HFP number) 18-1

# Communicating Your Comments to IBM

**Title:** IBM z/Architecture Principles of Operation

**Publication No:** SA22-7832-10

If you especially like or dislike anything about this book, please use one of the methods listed below to send your comments to IBM. Whichever method you choose, make sure you send your name, address, and telephone number if you would like a reply.

Feel free to comment on specific errors or omissions, accuracy, organization, subject matter, or completeness of this book. However, the comments you send should pertain to only the information in this manual and the way in which the information is presented. To request additional publications, or to ask questions or make comments about the functions of IBM products or systems, you should talk to your IBM representative or to your IBM authorized remarketer.

When you send comments to IBM, you grant IBM a nonexclusive right to use or distribute your comments in any way it believes appropriate without incurring any obligation to you.

If you are mailing a reader's comment form (RCF) from a country other than the United States, you can give the RCF to the local IBM branch office or IBM representative for postage-paid mailing.

- If you prefer to send comments by mail, use the RCF at the back of this book.
- If you prefer to send comments by FAX, use this number:
  - FAX: (International Access Code)+1+845+432-9405
- If you prefer to send comments electronically, use one of these network IDs:
  - Internet e-mail: [mhvrfs@us.ibm.com](mailto:mhvrfs@us.ibm.com)
  - World Wide Web: <http://www.ibm.com/servers/eserver/zseries/zos/webqs.html>

Make sure to include the following in your note:

- Title and publication number of this book
- Page number or topic to which your comment applies

Optionally, if you include your telephone number, we will be able to respond to your comments by phone.
